IDENTIFIERS	*Pacific Region

ABSTRACT

This volume includes the papers presented at the 1992 conference of the Pacific Telecommunications Council (PTC), which focused on challenges of regional telecommunications integration. The more than 150 papers in this collection represent a wide range of interests, locales, and perspectives. Satellites were of special interest to discussions about regional integration of telecommunications in the Pacific, and many of the papers focus on the world's major communications satellite providers, innovative applications for satellite services, technical explanations of satellite capabilities, and proposals for new satellite networks. Attention is also directed toward mobile communications, which present numerous opportunities for augmenting many nations' limited telecommunications infrastructures and meeting new demands throughout the Pacific region. Policy considerations, the implications of regulatory frameworks, information networks and systems, observations on strategic alliances, and insights on investment and financing were also highlighted. Papers are indexed by paper number, subject, country, and author. Most provide their own abstracts and bibliographies. Thirty papers that arrived too late to be included in the bound proceedings volume have been appended to it. (DB)

THE PACIFIC TELECOMMUNICATIONS COUNCIL

PTC'92 is organized by the Pacific Telecommunications Council, and international non-governmental, non-profit organization. The council is regional in nature, embracing members from all the countries that play a role in the development of Pacific telecommunications. Its 319 members from Industry, Academia and Government are dedicated to promoting the understanding and beneficial use of telecommunications throughout the entire Pacific Hemisphere--North, Central, and South America, East, South and Southeast Asia, Australia, New Zealand, Melanesia, Micronesia and Polynesia.

Foreword

This volume includes the bulk of the papers presented at PTC '92, the 14th annual conference of the Pacific Telecommunications Council (PTC). The conference, entitled Regional Interests and Global Issues: The Challenge of Telecommunications Integration for the Pacific, focuses on challenges of regional integration.

PTC's annual conference provides information on current developments in the telecommunications sector and offers a neutral forum for the exchange of a wide range of viewpoints. Like the council itself, the authors whose papers are included in this volume represent a wide range of interests, locales, and perspectives.

While each year's conference is based upon a theme, inevitably the final content of the gathering also reflects the current concerns of telecommunications professionals throughout the region. This year's Proceedings illustrates that, once again, the annual conference serves as a spawning ground for ideas and promotes discussion about issues in the region.

Of special interest to discussions about regional integration of telecommunications in the Pacific are satellites. PTC '92 includes presentations concerning many of the world's major satellite providers, innovative applications for satellite services, technical explanations of satellite capabilities, and proposals for new satellite networks. Supplementing the focus on satellites is attention directed toward mobile communications. These technologies present numerous opportunities to augment many nations' limited telecommunications infrastructures and to meet new demand throughout the region.

Policy considerations, the implications of regulatory frameworks, observations on strategic alliances and the business dynamics of joint ventures, and insights on investment and financing are other concerns highlighted at PTC '92.

Of important note, PTC's entire series of annual conference Proceedings published since PTC '79 documents many developments in telecommunications and provides a time-series record of the evolving concerns in the ever-changing telecommunications industry.

The PTC '91 Proceedings featured, for the first time, a subject index. The concept has been refined for the PTC '92 Proceedings. First, through the creation of a supplemental index helpful in identifying papers that profile conditions or projects centrally tied to various countries and, secondly, through the addition of an index to authors, one can easily access single or multiple authored papers.

Due to a very tight production schedule, the papers are indexed by paper numbers, rather than by page numbers. Therefore, to facilitate expeditious location of materials, the indexes appear immediately following the table of contents.

An important feature of PTC '92, as at past annual conferences, has been the working groups included in the conference program. This year, the Proceedings includes background papers submitted in advance of the working groups. They appear following papers presented during regular conference sessions. Although the working groups background papers are included in the table of contents, they are not indexed with the regular session papers.

Author Index

Sunday, January 12, 1992

Monday, January 13, 1992

5 Global Networks: The Challenge of Creating a Global Network *2.1.1.3*
Hiroshi Ichihara

12 Cooperation and Competition: the Role of Strategic Alliances in the Trend Towards Globalisation *2.2.1.1*
David Gibbs

20 Joint Venture or BOT: The Choice for Telecommunications Development with Foreign Involvement *2.2.1.2*
John K. Slaughter

27 The North Pacific Cable - Charting a Course for International Alliances *2.2.1.3*
David Walker

30 Graphical Communication Network Simulator *2.2.2.1*
H.W. Chan

38 Various Methods of LAN-WAN Connection *2.2.2.2*
Satoru Urata

43 Switching of a Request Towards a Destination Address According to its Semantic Contents *2.2.2.3*
Jean-Jacques Mercier, Laurence Redon

48 Synchronizing the Evolving Network *2.2.2.4*
Rob Avery

56 Architecture for a Large-scale Digital Mobile Communications Network *2.2.2.5*
Mitsuaki Hanaoka, Akihisa Nakajima, Fumio Kondo

N/A Voice Enhanced Applications Enabled Through the Use of an Application Program Interface *2.2.2.6*
Daniel E. Stone

61 Rural Telecommunication Services in Malaysia *2.2.3.1*
A.R. Tharek

66 Papua New Guinea Telecommunication Network Development *2.2.3.2*
N C Mobiha

70 Satellite 'Cellular' Telecommunications User, my Experiences & Problems In a Mobile Society Improves the Pacific Hemisphere Cultural Growth and Development *2.2.3.3*
Angel A. Navarro, Marcela Z. Navarro

74 Telecommunications 2000 in Korea: Videotex Trial and Policy Implications for the Promotion of Informationalization of Society *2.2.3.6*
Gwang-jub Han, Woo-Hyun Won

86 Three Men in a Tub *2.2.4.1*
Robert E. Button

90 The Impact of New Broadcasting Technologies on Development *2.2.4.3*
Richard L. Nickelson

98 The Possibility of Unified Legal Infrastructure on Electronic Information Transfer (Communications in General) *2.2.4.4*
Nobuhiko Shimasaki, Mitsuo Kajitani, Susumu Shirasawa

108 Introducing Fiber Optics into the New Towns of the 21st Century *2.2.4.5*
Thomas A. Reiman

115 The Commercialization Of Space *2.2.5.1*
Linda M. Rankin

119 Strategies For Market Entry By International Separate Systems *2.2.5.2*
Robert M. Frieden

N/A Satellite Program Distribution in the Pacific *2.2.5.3*
Veronica M. Ahern, Albert Shuldiner

126 Satellite Data Broadcasting System *2.2.5.4*
Toshiro Mizokuchi, Kochi Yamakawa

134 A Communications Platform for Road Traffic Management *2.2.6.1*
Darryl King, Paul Gale, Maxwell Lay

141 A New Traffic Information Service Delivered Over the Cellular Mobile Phone Network *2.2.6.2*
Yukio Ouchi, Seiji Suzaki, Toshio Nishiyama, Masanobu Higashida

148 The Airline Industry: Major Customer and Innovator on the Thin Routes of the Pacific *2.2.6.3*
Daniel C. Smith

154 Tourism in a Global Context: The Case of Frequent Traveler Programs *2.2.6.4*
Hamid Mowlana, Ginger Smith

COUNTRY INDEX

(Underlined session numbers in this index indicate that a country profile is provided; all others concern the nation or region in regard to individual projects or within the context of a comparative analysis. U.S. originated projects are not indexed by country here unless they involve another nation or region.)

Australia 2.2.1.1, 2.3.1.1, 3.2.6.1, 4.2.1.3, 4.2.4.2, 4.3.3.1, 4.3.6.5

Brazil 2.3.1.1, 3.2.1.1

Canada 2.2.5.1, 4.3.6.4

China, People's Republic 2.3.4.3, 3.2.1.1

Europe 2.2.1.1, 2.3.1.1, 2.3.5.1, 3.2.4.1, 3.2.7.2, 4.3.1.5

France 2.3.1.1

Germany 2.3.1.1

Hong Kong 2.2.1.2, 4.2.4.4

India 3.2.1.1

Indonesia 2.3.4.2, 3.2.1.1, 4.2.2.3

Italy 2.3.1.1

Japan 2.2.1.1, 2.2.2.5, 2.2.5.4, 2.3.1.1, 2.3.2.3, 2.3.4.3, 3.2.1.3, 3.2.2.2, 3.2.3.3, 3.2.5.2, 4.2.8.1, 4.3.6.5

Korea 2.2.3.6, 2.3.1.1, 2.3.1.5, 3.2.3.4, 3.2.7.4, 4.3.3.3

Latin America 2.3.1.1, 3.2.1.1

Malaysia 2.2.3.1, 3.2.3.5, 4.3.3.4

Mexico 2.3.1.1, 3.2.1.1

Micronesia 3.2.5.3

New Zealand 4.2.1.3, 4.2.4.2

Pakistan 2.2.1.2

Papua New Guinea

Peru 3.2.1.1

Pacific Island Nations 3.2.4.5, 3.2.5.3

Philippines 2.2.3.3, 3.2.3.6, 4.3.3.5

Singapore 3.2.5.2

Sri Lanka 2.3.5.1

Taiwan 2.3.1.1

Thailand 2.2.1.2

Tonga 3.2.4.5

United Kingdom 3.2.7.2, 4.2.4.2

U.S.S. (formerly U.S.S.R.) 3.2.7.2, 4.2.1.6

Global Networks
The Challenge of Creating a Global Network

Hiroshi Ichihara
President
Kokusai Denshin Denwa Co., Ltd. (KDD)

Socioeconomic changes in the world make the countries in the world more and more interdependent on each other. Telecommunications are required to play a catalytic role to develop this trend further. KDD is making an effort to meet this requirement by offering to customers end-to-end services. This paper describes how KDD is aiming at achieving this objective.

1. Introduction

The changes taking place in today's world are truly revolutionary. The tearing down of the Berlin Wall was one of the most dramatic in a series of events that led to the easing of East-West tensions and political transformations whose repercussions will be felt for decades, if not centuries, to come. At the same time, the increasingly "borderless" activities of corporations everywhere have ushered in a new era of globalization and growing interdependence in every aspect of business and economics. As a consequence, we are witnessing an expansion in the scale and scope of human activity that is unprecedented in history. Inevitably, the spotlight is now on communications in the true sense of the word. This, in turn, is accentuating the importance of international telecommunications, which have always been the primary means by which people have communicated over international boundaries.

KDD's response to these dramatic events has been to initiate the development of a global network designed to provide end-to-end customer support. I would like now to take a closer look at some of the actual steps we are taking.

2. Streamlining the International Trunk Communications Network.

There are two types of international telecommunications networks, satellite and cable, but in my talk today I shall focus on the transpacific submarine cable network.

The bed of the Pacific Ocean already accommodates many submarine cables, as you can see from the first figure. Of these, optical fiber submarine cables have played a particularly significant role in handling the rapid increase in telecommunications traffic across the Pacific.

In April 1989, KDD and twenty-nine other telecommunications carriers from fifteen countries around the globe joined together to begin operating HAW-4/TPC-3, the first optical fiber transpacific submarine cable. On a 64 kbps conversion basis, its capacity is equivalent to 7,560 circuits, making it the core of the current transpacific network.

However, the rapid increase in the volume of telecommunications has made it necessary to construct a new cable, TPC-4, which is scheduled for completion in October 1992. This optical fiber submarine cable will also have a very large capacity: on a 64 kbps conversion basis, its capacity will be equivalent to 15,120 circuits. As I am sure you know, optical fiber submarine cables have higher quality and larger capacities than conventional coaxial cables, so they have become an indispensable means of meeting the rapidly growing demand for telecommunications capacity across the Pacific Ocean. Nevertheless, the astonishing increase in transpacific telecommunications traffic means that even when the new cable mentioned above comes into operation, there will not be sufficient capacity.

For this reason, plans for the construction of TPC-5CN are already well advanced. TPC-5CN will be constructed of high-volume optical fiber submarine cables providing, on a 64 kbps conversion basis, a capacity equivalent to 60,480 cir- cuits in a two-pair configuration connected in a loop. In fact, the TPC-5CN's design incorporates a revolutionary new concept - the self-healing system - which is illustrated in Figure 2. When a conventional submarine cable breaks down, we have to rely on satellite circuits or other cables for back-up until it is repaired. In contrast, each cable in TPC-5CN has its own independent back-up one on cable. By using two pairs for the circuits, the spare pair can take over for the first pair should it break down. Constructing the cables in a loop configuration allows transmissions to be switched to other cable on the loop should faults develop in both pairs.

Figure-1

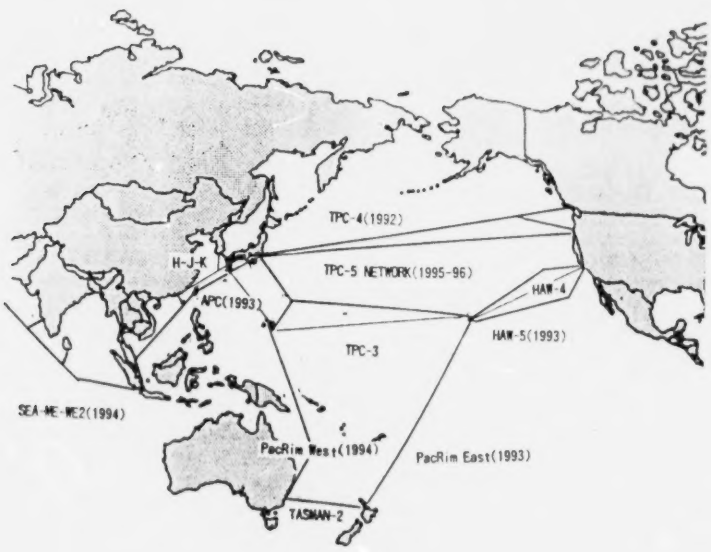

Figure-2

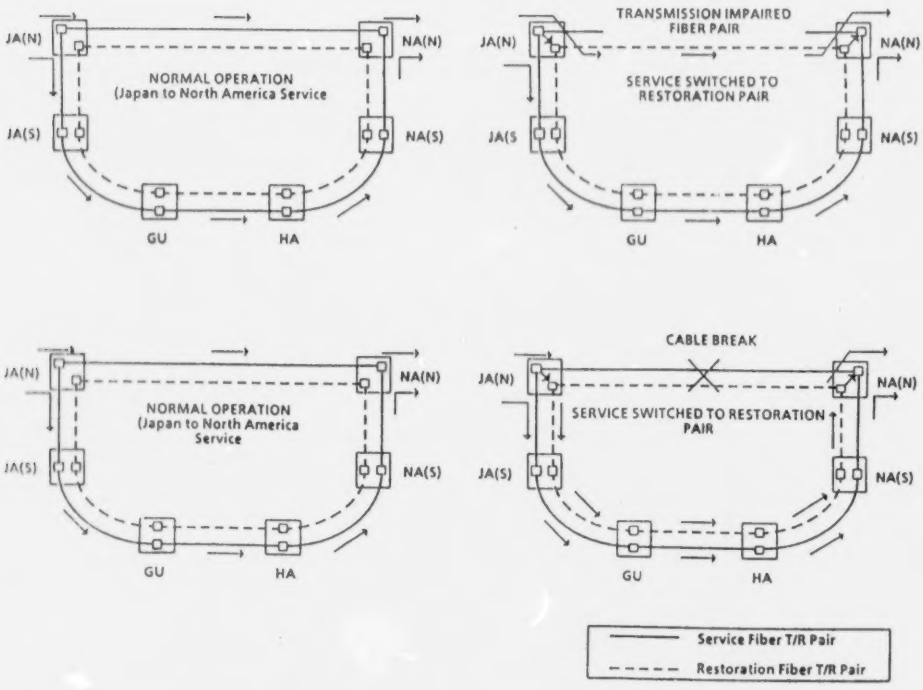
TRAFFIC DIVERSITY AND SELF-HEALING FIBER-ON-FIBER RESTORATION



Because the system permits instantaneous switching through the same transmission medium, it allows the provision of a secure and highly reliable network. Any future plans for laying optical fiber submarine cables are bound to place as much emphasis on security and reliability as on capacity.

Ordinarily, the optical signal transmitted inside the cable attenuates with the distance it travels, so that at set intervals it must be converted to an electric signal and regenerated. This requires submersible repeater. KDD has developed the technology to simplify repeaters in such a way that they amplify the attenuated optical signal as light without converting it to an electric signal. Because these simplified repeaters have fewer components, they are expected to provide greater reliability and allow larger signal volumes to be transmitted. Naturally these repeaters will be used in the TPC-5CN cable. More details of the new optical amplifier will be given at another session.

When, constructing an optical fiber submarine cable, it is important to increase the reliability of the cable itself, but more important is its maintenance; the maintenance system which enables rapid repair and quick restoration of the traffic when breakdown occurs. KDD is presently building a new cable ship, the KDD Ocean Link, which is scheduled in commission in February 1992, in addition to the KDD Maru which KDD presently uses for laying and maintaining submarine cables. She will carry the latest cable-laying equipment and a large-capacity cable tanks that will allow her to lay about 4,500 km of cable at one time. She will also be made highly maneuverable so as to facilitate the laying and repair of cable under the harsh ocean conditions of the North Pacific.

KDD has thus adopted an overall approach to building and improving the international trunk network which not only ensures that sufficient capacity is in place to handle telecommunications traffic, but also provides safer, more reliable circuits with an established maintenance system.

3. Improving the Domestic Telecommunications Network of the corresponding countries

When international telecommunications are seen as end-to-end services, it is obviously important to take the domestic network of the corresponding countries into consideration as well. The condition and status of domestic networks vary widely from country to country. In some countries, expanding or enhancing domestic networks to meet customer demand requires such vast sums of cost that a single enterprise cannot possible provide the finance. KDD is active here, too. As mentioned at PTC '91 last year, KDD, AT&T and the Ministry of Posts and Telecommunications of People's Republic of China are working together on the PRC Digital Network Project, for example.

International telecommunications between Japan and China are currently handled by an Intelsat satellite and by the Japan-China submarine cable. Demand for high-quality digital transmission is growing among the users in China, however, the cable is expected to reach full capacity by the mid 1990s. It is thus imperative that the domestic and international telecommunications networks be improved.

The PRC Digital Network Project was designed to meet this need. As illustrated in Figure 3, the first stage of the project calls for the use of local distribution radiowaves (LDRs) that employ digital microwaves to provide direct links between buildings in which customers are concentrated and an IBS urban gateway earth station installed on the roof of a Ministry of Posts and Telecommunications building. Digital leased circuit services will be provided via the Intelsat satellite over the Pacific Ocean.

This project will enable high-quality international digital transmission paths to be established via satellites in a short period of time. By redirecting international traffic that was previously handled on the domestic telecommunications network to these new links, the scheme will do much to reduce the burden on the domestic network. Services are expected to begin in the very near future.

As an extension of this project, the second phase calls for the construction of a Japan-China optical fiber submarine cable, which is scheduled to go into operation offering full-scale digital transmission services between Japan and China at the end of 1993.

While each country is basically responsible for building and enhancing its own domestic networks, one of KDD's goals is to contribute by making its technology available to countries that need it.

4. Services Provided with over the enhanced networks

Telecommunications services are faced with the task of satisfying a rapidly

diversifying range of customer needs. Simply providing transmission routes does not meet the demand for full end-to-end services. To cope with the situation, KDD has adopted a number of approaches, particularly with regard to corporate customers whose needs are especially diverse and sophisticated.

It is becoming increasingly clear that in order to operate in the borderless international market, today's businesses require high-capacity networks that provide real-time global links around the clock. At the same time, as they begin to use telecommunications in a more sophisticated manner, the construction of an efficient corporation network is an important part of any corporation's business strategy. As a result, corporations are not only demanding safer, more reliable networks, but are also moving toward integration of voice, images and data in a multi-media environment.

Another key trend in the creation of corporate telecommunications networks is "outsourcing." Corporations are finding it makes sense to concentrate on the areas of business where they are strongest, and entrust the implementation of networks and systems to the telecommunications providers who possess the necessary advanced technology and know-how. To meet this trend, KDD offers a line-up of the services called "KDD PLANS" which provide customers with comprehensive support for a wide range of networks, as shown in Figure 4.

As part of these services, KDD recently started offering the integrated network management service PLAN-M. Network monitoring equipment installed on KDD's premises provides total systems management and maintenance for customers, end-to-end, between Japan and abroad. PLAN-M deals with breakdowns speedily and makes it easier to control and analyze service quality. The SYSTEM-PLAN network service, on the other hand, lets customers use a system constructed on KDD's premises to build their own made-to-order system, while the PORT-PLAN network service provides a ready-made network by connecting the required customer cir-cuits to a system on KDD premises. As part of another service, PLAN-H, KDD provides space on its own premises for customers who want to build a network with their own telecommunications equipment, and monitors, operates and maintains the equipment on the customers' behalf. Finally, under PLAN-E, KDD makes use of its own expertise in a consulting engineering service to support customers designing their own networks.

By using these services, customers can create more sophisticated networks in shorter timeframes with greater safety. Combining the services increases the benefits of implementing networks that use integrated management, thus enabling KDD to provide finely honed services that meet customer requirements exactly. Many of KDD's customers are already enjoying the benefits of these enhanced services.

At the same time, KDD is introducing new features to meet demand for more sophisticated capabilities in public networks. Using the optical fiber submarine cables and digital satellite technology described earlier, KDD now offers international ISDN service to 11 countries, including the United States, Britain, France, Australia and Singapore, with service areas to be expanded in the future. KDD's next step will be the introduction of broadband ISDN service which should help satisfy the growth in demand expected to result from heavier traffic, such as in highquality audiovisual communications.

By providing an array of databases in the network, KDD can also provide services that offer higher added value. KDD already provides intelligent network services such as Auto-Credit Card Call and Free-Phone Service. Most recently, it has started providing international Virtual Private Network (VPN) services. These services allow customers to "tell" the network how they want to pay charges, dial destination numbers, and so on. Although these services are still at a rather primitive level, we consider them an important first step toward full-scale intelligent network services that include UPT service.

These endeavors are designed to transcend the ultimate dream of "face-to-face" telecommunications by providing tools that help people and implementing a global network that is intimately intertwined with human activities.

5. Global Carrier Cooperation

One critical factor in the programs and endeavors I have discussed to this point is the vital importance to the implementation of a global network of international cooperation and linkages between carriers. Obviously KDD cannot do it alone.

For international end-to-end telecommunications, the carriers in the originating and destination countries must work together. There are two possible types of carrier tie-up classified in line with the implementation of a global network. The

Figure-3

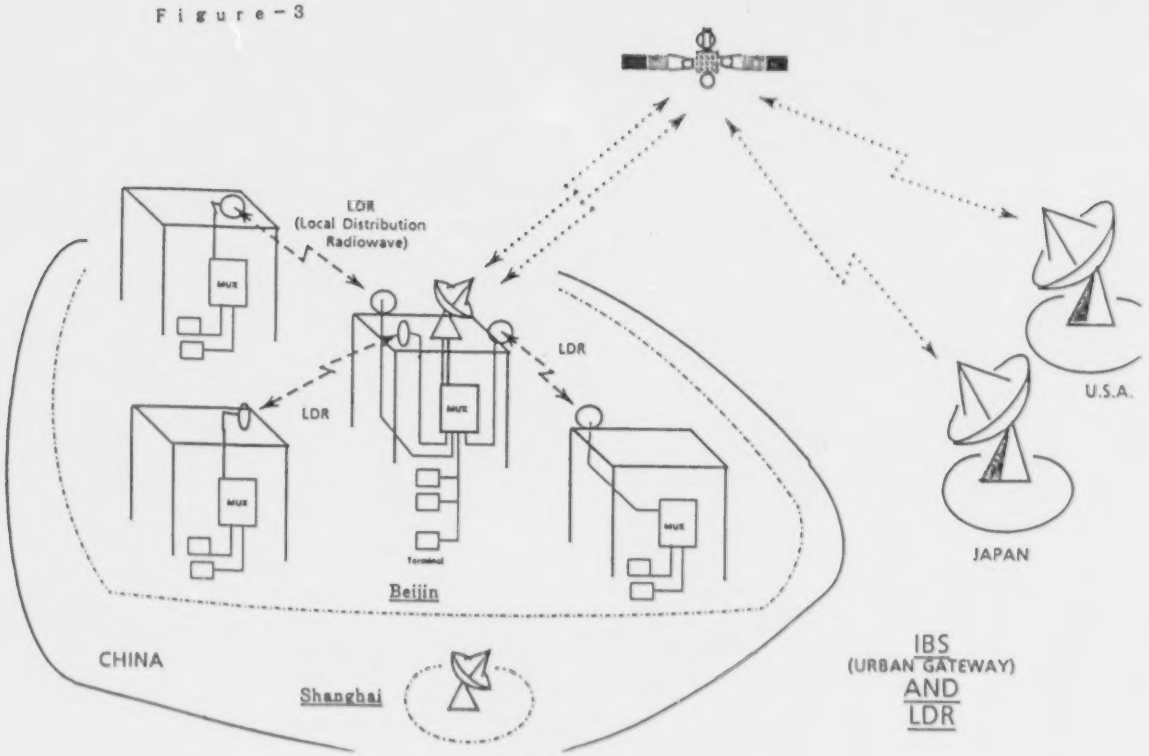


Figure-4

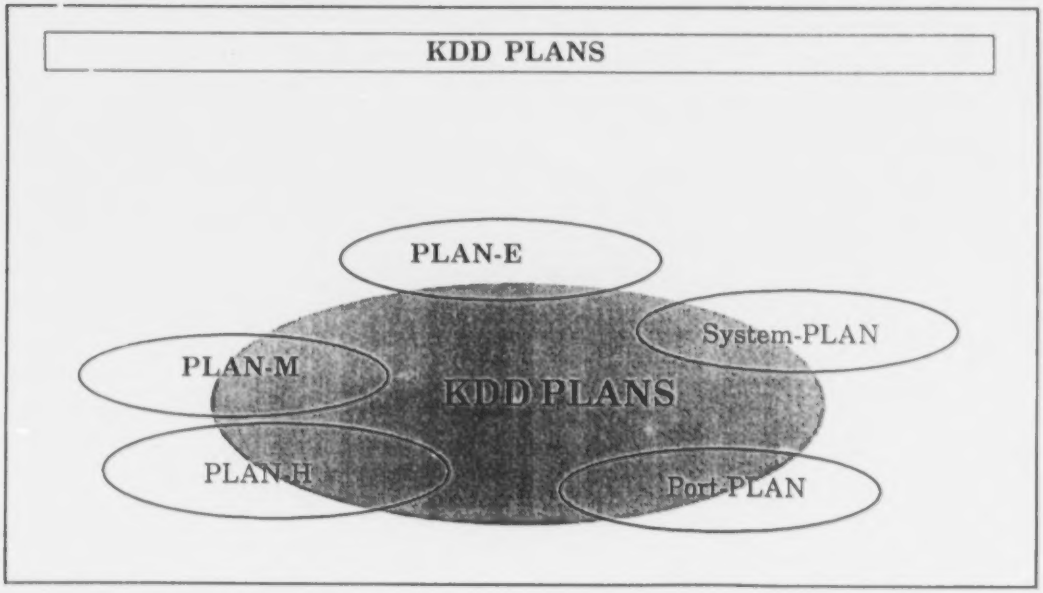

first is characterized by the construction of the trunk line networks themselves, such as optical fiber submarine cables, or the establishment of carrier tie-up in the implementation of ISDN. An example of the second is the provision of services by groups of multiple carriers under joint brand names. This has been a particularly promising method of expanding new services and is making a major contribution to the globalization of such new services.

One service that KDD offers using the latter format is "one-stop shopping," which enables customers to integrate any requirement to a single contact point of carriers within the framework of the international leased circuit service and many customers have made use of this service. One project has been recently started. This is a joint effort between certain carriers, including KDD, to set up an international telecommunications network that provides worldwide support to multinational corporations. Customers who wish to implement an international network employ those carriers to put together a lateral, joint project team that provides circuits, delivers, maintains and operates equipment, and manages the network. This system guarantees end-to-end telecommunications, integrates all points of contact when the network is set up, and delivers higher quality services with a shorter set-up time. Further joint projects with overseas carriers are also under consideration at KDD.

In addition to this type of tie-up, KDD works through the KDD Group's overseas subsidiaries, as illustrated in Figure 5, to provide end-to-end customer support in the form of consulting and other services.

In the context of implementing a global network, it is also vital not to overlook the importance of technical assistance to developing countries. Cooperation with developing countries is an essential element in the planning, creation and extension of the telecommunications infrastructure to ensure greater universality and compatibility in the sphere of international telecommunications. KDD has long been active in such assistance and will continue to work with developing nations to improve their international telecommunications.

6. Conclusion

To conclude, KDD is working toward the construction of a global network through the many projects in which it is involved. These include the building of a trunk line system for domestic and international communications that incorporates maintenance and operational functions, responding to corporate demand for more sophisticated services that utilize these networks, incorporating more intelligent features into a wider portion of the network itself, and working globally with other carriers on the development of the new technologies necessary for the proper implementation of these projects. In light of the revolutionary changes taking place in international society today, the provision of end-to-end services is vital to ensuring communications in the truest sense of the word. We look forward to facing these continuing challenges.

Cooperation and Competition: The Role of Strategic Alliances in the Trend Towards Globalisation

David Gibbs[1]
McKinsey & Company
Melbourne, Australia

Globalisation and strategic alliances are the subject of much debate in the telecommunications industry. This paper explores the drivers and constraints of both subjects and outlines the impact that strategic alliances are likely to have on the trend towards globalisation.

Globalisation is the catchcry of the 1990s. It is a growing trend, especially in the area of telecommunications traffic carriage, which has prompted considerable debate within the telecommunications industry. Much of the debate centres around the emergence of strategic alliances involving domestic telecommunications companies (telcos) which have traditionally operated within a legislative framework that fosters cooperative agreements with other national telcos. Today, in the climate of globalisation and increasing competition, this is changing. Telcos are beginning to explore new ways of operating in their search for ways to gain the benefits of the globalisation trend.

Within the international arena, many telcos are behaving as if they believe that the current changes to the industry structure will lead to the emergence of a few truly global telcos. It is unclear, however, within the volatile industry structure whether any telcos have a clear recipe that will guarantee both the globalisation of the industry and their sustainable role within it.

This paper extends the current globalisation debate by bringing into focus the issues faced by strategic alliance participants, both prospective and established. It argues that success or failure in managing these issues will have a significant impact on the telcos' present vacillation between the old ways of cooperation and the new ways of competition.

To fully develop these arguments, this paper is structured around four themes. These are:

The traditional industry structure which forced cooperation between telcos

The impact of recent market developments, particularly the globalisation trend, on encouraging rivalry

The opportunities or constraints offered by strategic alliances within this framework

The winners and losers in the 'end game' of these developments.

1. HISTORIC TRADITION: FORCED COOPERATION

Many of the issues faced by telcos today—in particular, those surrounding the globalisation debate—stem from the traditional industry structure in which domestic monopolies operated within country boundaries and cooperated to provide international services. Understanding the drivers of this structure is important background to understanding today's instabilities and likely longer-term issues and outcomes.

1.1 NATIONAL PRIORITIES DICTATE DOMESTIC MONOPOLIES

Traditionally, the telecommunications industry has been characterised by high capital investments in basic domestic infrastructure offering long, and sometimes infinite, payback periods. Typical projects, such as developing the Customer Access Network, cost billions of dollars and provided returns over 20 to 30 years. To ensure these investments were made so that the entire population received telephone facilities, even in uneconomic cases, telcos developed as domestic monopolies in public ownership.

This not only provided government and regulatory support for the development of telecommunications, but also recognised that telecommunications was of national strategic importance and should be managed for the interests of the nation as a whole—not just for the profits of the telco. Only through these protected, monopolistic domestic industries could the multiple objective functions required for successful infrastructure development be managed. These objectives typically included providing telephone services at a loss to those who could not afford them and supporting the development of a local equipment supply industry. While many governments believe their telecommunications development has moved beyond this phase, we must recognise that some are still grappling with the problems of providing basic telecommunications to their populations.

This monopolistic approach suited isolated domestic markets where the government or regulator could provide stable operating conditions and could ensure a sufficient return on the high levels of investment involved. It was not suited to the international scene.

1.2 FORCED COOPERATION FOR INTERNATIONAL TRAFFIC

While investment in the development of international telecommunications was as large—and significantly more risky—as the domestic network, there was no 'global' government or regulator to manage development. Thus, development of international communications, particularly between continents, had to result from cooperation among the domestic carriers for international infrastructure development and traffic carriage.

This cooperation was formalised under long-standing bilateral agreements between telcos and, in some cases, nations. These agreements aimed to share the risks of major investment evenly among the telcos involved. They existed at many levels, for example:

Consortium of many telcos supporting the capital and operating costs of intercontinental satellite and fibre optic investments. The formation of the International Telecommunications Satellite Organisation (INTELSAT) in 1964 proved the high point of cooperation among telcos on this dimension. A multilateral body, INTELSAT aimed to administer and develop the emerging satellite communications infrastructure. Most governments throughout the world signed the agreement, considering such cooperation essential if the enormous investment in new satellite technology was to be achieved without undue risk being placed on individual carriers.

Revenue-sharing agreements for switched traffic carriage, whereby the originating carrier paid the terminating carrier a predetermined portion of the customer tariff–typically 50 percent in the early days. These long-standing agreements underlie the 'accounting rate system' as it is known today.

Split responsibilities for international private lines where each carrier took responsibility for billing and maintenance on their half of the circuit.

These agreements provided a stable, collaborative framework which supported the development of international infrastructure and services between national markets with monopolistic carriers.

2. MARKET DEVELOPMENTS: GLOBALISATION ENCOURAGES RIVALRY

The 1980s, however, witnessed several developments in telecommunications. Among these, it was the rapid decline in international infrastructure costs (particularly fibre optic cables) and the introduction of competition in national markets that placed the most strain on the collaborative industry structure.

Between 1983 and 1991 alone, the cost of installing transatlantic cable capacity fell from around US$1.5 million per Mbps to US$0.4 million per Mbps. Cultural and policy differences between countries resulted in differing lag times between the resulting decreases in transmission costs and decreases in the tariffs charged to consumers. This, combined with the rigidity of the accounting rate regime for switched traffic, meant the agreed outpayment to the terminating carrier began to act as a constraint on reducing consumer tariffs. These outpayments, which were frequently fixed for 5 years or more, rapidly became outdated as transmission prices plummeted. The result was the development of substantial traffic imbalances. For example, between 1978 and 1986, when US and German carriers paid each other on the basis of an accounting rate that remained fixed, US tariffs for carrying an 8-minute call fell from about US$17.50 to US$10.00, but German tariffs remained unchanged. Not surprisingly, this led to a substantial shift in traffic. By 1986, the volume of traffic from the US to Germany had increased to more than double the volume from Germany to the US.

These imba[illegible]ces, which affected the profitability of carriers and their host nation's current account, were exacerbated by the introduction of c[illegible]tition in the US, UK and Japanese markets in the early 1980s. Competition had two major impacts. First, with two or more carriers now bidding down each other's tariffs, the rigidity of the accounting rate regime became untenable. Second, telcos could consider operating in more than one domestic market. While historically regulation had limited their offshore activities to resale (where allowed) and the provision of value-added services, a selected few could now officially take advantage of the opportunities to provide basic services offshore.

The introduction of competition is seen in both developed and developing economies. The developed economies seized competition not only as an opportunity to take advantage of plunging technology costs and the rapid rate of new product innovations, but also as an opportunity to frighten their incumbent telcos, frequently regarded as inef[illegible]cient, into removing inefficiencies.

In contrast, developing economies, realising the importance of a reliable and technologically-advanced telecommunications network in building economic growth, are attempting major upgrades of their networks. Starved of cash to develop major infrastructure on their own, they look increasingly to foreign telcos and other investors to assume the responsibility and financial burden of developing their domestic networks.

Against these rapid changes within the industry, telcos and, in some cases, countries have exploited the inevitable restructuring and are operating in a global environment outside the jurisdiction of any truly international regulator.

The approaches taken to exploit these opportunities are increasingly diverse, but are limited in their effectiveness by a challenging set of constraints.

2.1 EXPLOITING OPPORTUNITIES

A combination of greed by telcos restricted domestically, fear by those threatened domestically, and obedience by those directed by some greater national priorities, has seen the emergence of two broad groups of international initiatives: those aimed at increasing domestic sources of telecommunications traffic and those aimed at supplementing domestic customer bases with offshore ones.

2.1.1 INCREASING DOMESTIC TRAFFIC SOURCES

Astute telcos, and in a few cases countries, have recognised the potential to shift international telecommunications traffic patterns and have exploited the limitation of the present industry structure to their advantage. With the apparently high price sensitivity, as shown earlier in the US/German example, securing pricing freedom by escaping the traditional industry structure can yield benefits to net exporters of traffic who will keep an unevenly large share of private lines and outgoing switched traffic and make no payment to the terminating carrier. Hence, the quest for increased origination of traffic.

Approaches to increase domestic traffic sources have been at three levels. At the first level, attempts were driven specifically by telcos seeking private network hubs but, as infrastructure costs continued to fall, these attempts were extended to the second level, which involved undermining the broader bilateral agreements governing international switched traffic carriage. A third and complicating level has been the broader initiatives by countries which want to pursue commercial hubs. The three levels are discussed in more detail below.

Seeking private network hubs

The traditional way to capture international traffic revenues is through hubbing of private networks. Since each telco is paid for its half of an international private line, the one which can attract a hub gets many half circuits worth of revenue, while the telcos at the end of the spokes only get one each. Pricing and service are the primary levers used to influence a corporate's choice of hub.

Pricing is a straightforward and easily understood initiative. The service initiatives provided the start of 'one-stop shopping'—trying to overcome the need for a customer to deal with two telcos, one domestic and one offshore, to establish and operate a private line. Agency agreements provided early mechanisms to achieve this aim, but have rapidly been replaced by joint service and marketing agreements among telcos.

The recent emergence of Virtual Private Networks (VPNs) also affects the telcos' ability to provide 'one-stop shopping' internationally—in this case, by providing pseudo-private networks over an intelligent switched network.

Undermining bilateral arrangements

Due to infrastructure price reductions, large international telcos are capable for the first time of developing 'private' international capacity. This has led to the development, by a small number of essentially private consortia, of projects such as the private transatlantic satellites and cables. These developments—although perceived as risky—are positioned to have substantial long-term impact on the business if they are managed adeptly.

Telcos with private infrastructure and operating licences or agreements in multiple domestic markets will be able to sidestep the accounting rate regime—international traffic carriage between their markets effectively becomes an internal transaction. Even if accounting rates are technically applicable, it becomes nothing more than an internal transfer price that is irrelevant to the overall economics of the business. Telcos acting in this way will have greater freedom to exploit price elasticities and increase traffic origination through lower end-to-end call prices. Telcos that do not have this capability will remain bound by accounting rates and will be unable to respond without either reducing accounting rates to zero (a tough challenge) or incurring significant losses.

In addition, by driving tariffs down on thick routes, telcos with private infrastructure remove the scope for the current cross-subsidy from profitable thick routes to unprofitable thin ones. In the extreme, this could drive the INTELSAT consortium described earlier to become a form of global Universal Service Obligation. Nations with telcos too small to build their own international network would continue to rely on the system while the larger, richer telcos would build their own capacity and withdraw equity from the system. A possible end result is that INTELSAT will become a collective of poor nations and national telcos, unable to fund itself and unable to support the investment needed to maintain a serviceable infrastructure.

Pursuing commercial hubbing opportunities

Throughout the last decade, transnational corporations (TNCs) have expanded their operations through the development of global and regional headquarters (RHQs). Several countries are competing to attract TNCs and their RHQs in a bid to develop the pre-eminent regional commercial hub. This has moved well beyond private line hubbing as telcos and, increasingly, governments realise the significant benefits—in terms of employment, investment and the further development of a host services sector—which flow into the country if it is a favoured location for an RHQ. For example, it is estimated that the City of London, which has a hub based around financial services, employs 357,000 people and contributes over £20 billion to Britain's Gross Domestic Product.

Most Asia-Pacific governments have taken initiatives to position themselves as the natural choice for an Asia-Pacific RHQ. Singapore, in particular, has been pursuing TNCs through its Operational Headquarters Program, and through close cooperation between the Singapore Economic Development Board and Singapore Telecom. The city now promotes itself as a 'total business centre' and is careful to ensure that the cost and quality of its telecommunications services are attractive to TNCs.

While the cost and quality of telecommunications services are important characteristics which TNCs look for when deciding on where to base their RHQs, they also look for a number of other factors. These include: political and economic stability; quality of life; reliability, cost and skills of the local work force; extent of deregulation and/or bureaucracy and government incentives.

2.1.2 SEEKING OFFSHORE CUSTOMER BASES

Telcos that have taken advantage of every opportunity to increase domestic traffic sources may then turn to offshore customer bases as a source of additional revenue and profit. These telcos are motivated by a number of imperatives, including the desire to follow domestic corporates, the need to replace customers lost through competition and in response to supply chain pressures.

Following corporates

One natural source of offshore customer bases is the offshore arms of domestic corporations. As in many other businesses, either network or product, following captive domestic customers as they venture in foreign markets is a low-risk entry vehicle. The increasing propensity to outsource global networks and the much discussed trend of 'one-stop shopping' are no doubt adding momentum to this trend. For the US, Japan and UK (and possibly Germany and France), the nations which are home to the majority of the world's TNCs, this may well have potential as a sustainable vehicle.

Yet, looking beyond the euphoria-at the increasingly large effort and capital committed to these global network initiatives (VPNs, acquisition of data networks, private cable networks, joint marketing initiatives) and, at the end of the day, the relative sophistication of the target customers-we must question whether this is a viable long-term strategy for even the top telcos, let alone the 'also rans'. Will this be the rapid globalisation and shake-out of corporate banking revisited?

Replacing customers lost through competition

Telcos threatened by the introduction of competition into their previously cosy domestic markets know the experience is painful. With increasing focus and speed, the new entrants are relieving the incumbents of significant market share and, through targeted marketing, an even greater share of industry profits. Falling cash flows, competition for skilled resources and burdens inherited from the monopoly days require drastic action. Domestic efficiency and market stimulation programs help, but not to the extent needed to overcome the damage of a skilled entrant, or entrants. Devices like Least Cost Routers simply exacerbate the situation. One clear response to these pressures is to seek new offshore customer bases, which telcos hope will create scope for future growth, provide opportunities for retaliation and raise the potential for bypassing the constraints of the traditional industry structure. With the introduction of competition in developed and developing markets, the motivation and opportunities for this behaviour are increasing.

Spending cash reserves

While seeking offshore customer bases in response to domestic competition is an honest motivation, it is not the only one. Domestic regulation has left many of the world's significant telcos (such as the Regional Bell Operating Companies in the US) with significant, protected cash flows and, up until recently, limited outlets to spend domestically. There is only so much capital you can plough back into upgrading a network. What else is there to do but seek out offshore investments?

Regulations are shifting to lower these cash mountains but, while such protected 'rich kids' exist, the prime opportunities will be in high demand. This may or may not lead to premiums being paid, but it will lead to more rapid damage in deregulated markets by cash-rich attackers still protected by monopolies back home.

Responding to supply chain pressures

Concentration in the telecommunications equipment and application services industries may also contribute to the drive for offshore investment by carriers. Over the last 5 years, worldwide overcapacity, increasing expense of research and development, and the decline in industry profitability have contributed to a concentration among the major equipment suppliers. Alliances and common user group demands have also accelerated the concentration of application service providers, both in national markets and internationally. At the same time, the traditional dominance of national markets by monopoly telcos is eroding as competition is introduced. The equipment suppliers and application service providers are, hence, gaining increased bargaining power. Inevitably, as this value transfer swings away from the carriers providing the infrastructure, carriers will be forced to multi-domestic investment if they are to build the scale needed to contain or reverse the value transfer.

2.. OVERCOMING CONSTRAINTS

With all these opportunities, why don't we already have a global industry structure? These opportunities are appealing and, no doubt, frequently articulated around the boardrooms of telcos internationally. But a number of major hurdles must be overcome before any telco can exploit them successfully. Key among these hurdles are choosing the appropriate opportunities, persuading the stakeholders that returns outweigh the risks, and winning the battle for resources.

Choosing the appropriate opportunities from the myriad available is the first challenge. On one hand, this means making decisions about the type of opportunity. Should a telco participate in privatisation of an existing carrier, buy an operating licence, invest in a 'build, own and operate' scheme in a developing country, buy an existing private network or public value-added network or invest in private domestic infrastructure? What about some combination? Or should a telco acquire a telecommunications-related business (for example, a hardware or software provider) or build a reputation through project management or consulting? Estimates suggest privatisations alone will consume over US$400 billion over the next 5 years. On the other hand, it means making decisions about the type of technology. Should a network investment be in radio, mobile or fixed network technology? Further complications arise when the use of bidding partners or consortia are concerned. Are they necessary? What will they bring? Can they be trusted? How should the deal be structured?

Simply sifting through deals and investment strategies presented by the hardware manufacturers, banks and other interested parties, is a daunting task that confuses and intimidates many prospective entrants-and that is not where the real action is. Leading telcos are creating the most attractive deals, many of which require significant change to regulatory frameworks. Much like the commercial real estate industry-the deals ending in the public arena have already been well screened and rejected by the leading players.

It is easy to see how many telcos have trouble getting out of the starting gates.

BEST COPY AVAILABLE

Persuading the stakeholders, including senior management, the board of directors and the government, that returns outweigh the investment and risks is the second challenge. Many of these stakeholders have little or no international experience and they need reassurance that the risks, ranging from political and economic stability to physical work conditions, can be managed. Stakeholders have every right to be nervous, given the high capital and long payback periods in many of these investments–particularly for fixed networks and for privatisations. Some members of senior management may even simulate strong resistance–despite intellectual commitment–if the need arises to divert funds away from their own domestic investment programs.

Winning the battle for resources is the third challenge. This is tied up with the organisational quest for control, which is no doubt familiar to many of you: a separate international division or global business units? With an international investment division, at least initially, domestic business units have little incentive to free scarce resources for offshore ventures. In contrast, global business units are complex to control and can lead to multiple uncoordinated activities in a given region or country. Again, while intellectually the solution may be clear, the resistance to implementing it–particularly by a territorial management team–may be immense.

These constraints are not unique to telcos, but are exacerbated by the government and regulatory intervention experienced in telecommunications. Neither do they preclude action. They simply raise the entry barriers–potentially to where a crisis is necessary to overcome the 'domestic myopia' of telcos and their stakeholders.

3. STRATEGIC ALLIANCES: OPPORTUNITY OR CONSTRAINT

As we have seen, the continued introduction of competition in domestic markets, combined with rapid decline in international infrastructure costs, destabilises the industry and results in a shift in focus from domestic operations, through a transitory phase of 'domestic with an international flavour', to longer-term questions over the emergence of a global industry.

As this occurs, the industry structure and the rational behaviour of major participants within the industry structure is also undergoing major change. Traditional alliance behaviour, aimed at short-term reduction of risk and sharing of investment costs, has less relevance and existing relationships may become uncertain. Forward-thinking telcos can exploit this instability by becoming a part of, or forming, a 'new game' global alliance positioned to have a formative impact on the emerging industry structure and become a major participant in the global industry. In the extreme, this would lead to the vision of a 'Borderless World' (as outlined by Ken Ohmae, Chairman of McKinsey & Company, Japan) being realised in telecommunications. The current telecommunications concept of cities and countries separated by major distances would collapse, and cities and countries would all be seen as adjacent local call areas (a view published by Clem Doherty, a Director in the Australian office of McKinsey & Company and co-leader of our Asia-Pacific Telecommunications, Electronics and Media Practice).

There is, however, little evidence of successful alliances of this nature in the telecommunications industry, where alliances have played more specific roles and wrestled against many unique challenges.

3.1 ROLE OF ALLIANCES

Given the range and scope of international activity, and an equivalent range and scope of themes in alliances, it is not surprising to see that the end result is a complex patchwork of alliances and joint ventures, with emphasis on short-term issues. Few of these alliances have been used as vehicles to pursue multiple opportunities and even fewer could be considered a startling success–particularly on the scale needed to make a fundamental impact on the development of the industry.

Under the traditional industry structure, early alliances formed between telcos, and in some cases between telcos and equipment manufacturers, include:

Cooperation and equity agreements to build international capacity through undersea cable or satellites such as the original Trans-Atlantic Cables and the INTELSAT satellite consortium.

Cooperative bilateral agreements covering international traffic carriage and billing arrangements through the accounting rate regime.

Memoranda of Understanding for limited personnel and technology exchange.

Joint agreements on short-term, project based, research and development.

Long-term operating contracts between telcos and equipment suppliers to provide installation, maintenance and upgrade of equipment domestically.

These types of alliances are still being pursued in areas such as international cable and satellite investments, but forces are emerging in the industry structure to reduce their effectiveness.

More recently, alliances have been used to describe cooperation and operating agreements such as:

Consortia of telcos and local partners bidding for major foreign licence opportunities such as the Optus consortium, consisting of Cable & Wireless (C&W), BellSouth and local Australian partners AMP (an insurance company) and Mayne Nickless (a transport company), which has recently been awarded the second Australian licence.

Consortia of telcos, equipment manufacturers and local partners bidding for foreign mobile licence opportunities, such as the Unitel consortium, consisting of STC, US West, Thorn EMI, and Deutsche Telekom, which was awarded a PCN licence in the UK.

Consortia of telcos, equipment manufacturers and even large user groups, which developed alternatives to the 'official' international cables for semi-private use. For example, the consortium of C&W, C.Itoh, Toyota, Pacific Telesis, Merrill Lynch, Singapore Telecom and US Sprint, which developed the ASPAC cable linking Japan, Hong Kong and Singapore.

Consortia established to target foreign market niches, such as the AT&T, Hutchison Telecom consortium targeting Value-Added Network services in Hong Kong.

All of these, however, could only loosely be termed strategic alliances. As some combination of joint ventures, acquisitions and long-term contractual relationships, they are not genuinely strategic alliances. Ken Ohmae, in his book, 'The Borderless World', describes a true strategic alliance using the French word 'entente'–a friendly understanding between major powers. It is most typically used by leaders of nations operating towards a common cause–and leaders of nations rarely use joint ventures, acquisitions or long-term contractual relationships to formalise their understanding.

This is an important distinction and one we will return to as telcos' ability to achieve it, we believe, will be a major determinant of at least the speed and possibly the overall emergence of a global industry structure.

Before moving to this broader goal, however, we must step back and address the real constraints which face the current alliance activity.

3.2 CHALLENGES FACING ALLIANCES

Alliances between networked business pose inherent difficulties and telecommunications is no exception. Not only must telcos confront the traditional challenges which face alliances, but they must also face the specific challenges of being in a networked business.

3.2.1 TRADITIONAL ALLIANCE CHALLENGES

As a starting point, establishing and managing an alliance for the long-term benefit of both partners requires that the alliance be designed to meet specific strategic objectives and to incorporate structurally key elements that encourage flexibility, participation and commitment by both partners. Our principles for successful alliance design, and hence the challenges faced by any telco entering an alliance, are as follows:

Strategic objective. The form of the alliance, the chosen partner, the agreed ownership structure and the scope of alliance activity must be designed to meet the strategic objectives of each partner.

Mutual dependence. The alliance must become a critical part of the overall strategy for each parent, such that the partners have the utmost incentive to provide the commitment and resources required to make the alliance successful.

Alliance independence. The alliance must be of substantial size and be given sufficient scope to allow it to reach the critical mass necessary to develop 'a life of its own' and the ability to sustain itself without excessive reliance on the parents.

Capability to evolve. Mechanisms must be in place that either allow or enforce the parents to adapt the strategy and structure of the alliance to changes in the competitive environment.

Barriers to exit. Structural or operational barriers to exit that make it difficult or painful for any of the partners to walk away and establish an independent business also need to be in place.

Shared vision and rewards. Mechanisms that allow and encourage partners to develop a common vision for the alliance and share in the rewards and benefits of working together, regardless of the success of a specific venture, should also be in place.

Clearly, a challenging agenda and one containing many inherent conflicts. Careful design of the alliance and ongoing management of the tensions is not a trivial task–it takes valuable time and resources.

3.2.2 ADDITIONAL TELECOMMUNICATIONS-SPECIFIC CHALLENGES

If the challenges which face traditional alliances are not difficult enough, the trade-offs between shareholder and stakeholder motivations, the complexities in network businesses and the ease with which services can be replicated complicate alliances in the telecommunications industry even further.

Shareholder versus stakeholder

Alliances will be tested by the different objective functions of telcos. While a few telcos have now been partly or fully privatised, with their sole target being shareholder wealth, the majority are still government-owned and/or regulated and have much more complex objective functions. These objective functions include wealth creation, but also cover other burdens such as universal service provision, even if many of those services make a loss, and supporting domestic supply industries. These differing objective functions complicate the determination of an ownership structure and scope for the alliance that meets the objectives of both partners.

Complexity in a network business

As international alliance activity grows increasingly complex, the number and scope of the cross-interests rise. In a stable operating environment, such activity may well be sustainable. Internationally, however, as the pendulum swings from the cooperate to compete axis these cross-holdings become unstable. This instability is caused by a number of factors.

Self interest of telcos that can only follow their major corporate customers across borders so far without moving into other alliance partners' markets.

Self interest in alliances between equipment manufacturers and telcos where motivation and objectives are very different. The equipment manufacturers are motivated primarily by up-front equipment sales, while the telcos are motivated by ongoing network development and usage.

Increased competition in domestic markets increases telcos' desire to divert their domestic competitor by using the 'my enemy's enemy is my friend' dynamic. The potential effect of this on the complex international alliance relationships could be to destabilise the entire structure.

Instability in the current international alliance structure will result in a reduction in the effectiveness of existing relationships. It will potentially force telcos either to 'go it alone' or to form strictly-aligned major groups which would have the ability, through long-term relationships, to take advantage and influence the direction of the global industry structure.

Alliances advantages shortlived

In many industries, alliances can create advantage for their participants for many years-even though they are unlikely to last forever. This is not always the case in the complex networked business of telecommunications.

The current crop of global VPNs provide a good example. While the first of these was heralded as a world initiative capable of revolutionising the industry for those involved, it soon became clear that they could be copied. less than 2 years later, there are now multiple alliances, all involving multiple carriers and all offering similar services. None could be described as carving out a valuable and sustainable niche position and, more importantly for this discussion, as regulation changes none of them really need consortia to be effective.

End-to-end ownership of international infrastructure was similarly heralded as an industry restructuring initiative but has now become commonplace-all in the space of 4 or 5 years.

4. END GAME: LIKELY DETERMINANTS

As in any industry, the end game is tough to predict and is unlikely to be either black or white. Key issues, like the emergence of supranational regulators or the success of truly strategic alliances, will be the determinants of the timing and nature of globalisation within telecommunications. At the top level, we can foresee two extremes of possible outcomes.

An oligopoly of global telcos emerges as successful alliances create true strategic advantage for a select group of competitors, supranational regulators fail to emerge, and a series of cross-border moves, mergers and acquisitions occur.

Concentration of significant cross-border holdings in the hands of a few major telcos does not eventuate. Competition continues to be introduced in domestic markets, but regional and supranational regulators of carriers, combined with continued failure of alliances, prevent the formation of an oligopoly of global telcos. Infrastructure and arrangements for the carriage of international traffic will continue to be handled through multilateral agencies like INTELSAT and by cooperation between telcos.

The end game, however, is likely to be somewhere between the two extremes and dictated to some degree by the regional regulators already in place. If we think about regionalisation, and then globalisation, the determinants become clearer.

4.1 REGIONAL OUTCOMES

Regional outcomes, under the influence of very different regulatory forces, are likely to be distinctly different from global outcomes in both their process and end point.

A slow but managed transition is likely in Europe. Due to its geographic concentration and the harmonisation achieved through the European Community's 1992 initiative, Europe shows little potential to be anything but an orderly managed transition towards regionalisation in telecommunications. Eastern Europe may create a few ripples, but little more. The uncertainty in Europe is how fast the regionalisation will occur, particularly given the diversity of starting points of the member nations and how far the regulations will ultimately allow competition to spread.

A faster but still managed transition is likely in North America. North America will remain under the strict control of the FCC and amendments to the Modified Final Judgment governing the activities of telcos-albeit with a greater tendency towards litigation than in Europe. Having been through the first phase of regionalisation in long-distance traffic carriage, the impending deregulation of the Regional Holding Company monopolies will cause pockets of angst, but is unlikely to be allowed to degenerate to mayhem.

A managed transition is well underway in Japan. Many would suggest that Japan is not a region but it is of such significance, economically and geographically, that it justifies separate consideration. Japan's transition has been rapid but relatively ordered. In this case, rather than a single 'official' as in Europe or North America, the complex web of control under the Keiretsu and government intervention in managing the telecommunications industry will prevent major disruption. NTT and KDD may argue, but the introduction of competition, despite the major impact on the incumbents, has been orderly.

A messy, unmanaged transition is likely in the rest of the Asia-Pacific region, if regionalisation actually eventuates. The wide disparity in political and economic objectives, different stages of economic development and relative geographic isolation combine with the lack of any form of regional regulation or control to make development in the region highly unpredictable. More than anywhere else, the eventual outcome will be dictated by truly competitive forces-both at a telecommunications industry and national level.

4.2 GLOBAL OUTCOMES

The differences in regionalisation approaches and timing outlined above do not form an easy foundation for predicting the likely global outcome.

Alliances will be one of the key factors in determining the industry structure within these regions, particularly within the Asia-Pacific,and in linking regional activities together if an oligopoly of global telcos is to emerge. We have already seen that alliances are more troublesome to manage in the telecommunications industry than in any other industry and that their benefits are likely to be shortlived. Yet, to ensure globalisation,

alliances will need to be used to produce industry changes on a scale not yet witnessed. These changes include:

Changing the rules of international traffic carriage by cooperating across a wide range of international traffic routes to bypass the traditional industry structure and destroy the economics of telcos without end-to-end interconnectivity.

Sharing research and development efforts between telcos to develop the ability to implement proprietary, world leading network applications quickly.

Using international alliance activity to curtail the effects of competition in participant's home markets, through using dynamics like 'my enemy's enemy is my friend'. This is both key to securing domestic cash sources and possible given the lack of any single global regulator.

Gaining access to third-party markets by leveraging the combined resources of alliances and promising global connectivity, and increasing domestic traffic flows for the new market as a result.

Achieving these outcomes within strictly aligned alliance groups that do not lead to alliance partners cooperating in some markets while competing in others.

If these can be achieved, which is theoretically possible although unlikely in practice, globalisation of the industry will come a step closer. It is not, however, guaranteed. At least two other events could prevent its realisation.

First, a supranational regulatory body could emerge to block the development of global telcos. This is not an unreasonable outcome given the impact that an oligopoly of global telcos could have on the global industry structure and hence the damage they could do to the interests of the many smaller, less financially secure telecommunications economies.

Second, selected countries, particularly in the Asia-Pacific region, could act unilaterally to undermine globalisation. For example, a country could choose to offer free international calls. Clearly this could only be done through government ownership as it would mean major losses for the telco. A far-sighted government, however, may see how the telco's losses could be more than offset by benefits realised elsewhere in the economy. Imagine the boost it would give to the local business community, particularly value-added service providers, and to the ability to attract corporate RHQs. The flow through benefits to the government of increased business activity (e.g. employment, taxes) could be immense.

This is an unlikely outcome, perhaps, but if it happens it will bring chaos into the industry as newly-corporatised telcos will be unable to respond.

Hong Kong

1. ABSTRACT

Privatization of telecommunications is following varying evolutionary paths in different countries leading to a whole range of industry structures. The objectives of Privatization are identified and the way in which the varying structure meet these in the short and long term is summarized in a checklist.

2. THE FIRST STEPS TOWARDS PRIVATIZATION

In the past four or five years, what is accepted as the telecommunications regulatory norm has changed dramatically. Prior to that most countries had either a ministry department monopoly or, increasingly, a state-owned corporation formed from the ministry department. Already the first steps towards widespread privatization had been taken. UK and Japan had introduced rapid changes bringing in both private investment and competition. Several territories had enjoyed the fruits of private enterprise in telecommunications for many years of course - amongst these in the Asia Pacific Region were USA, Hong Kong, Fiji, Philippines, Bahrain, Yemen Arab Republic and Guam, joined more recently by Macau, Tonga, Solomons, Vanuatu , PRC and others. Not surprisingly the acceleration of this trend recently has produced divergent formulae which will not all meet the high expectations of customers and governments alike. Where have these formulae come from, how do they compare and which will attract the ongoing investment essential in the industry? This paper tries to answer some of these questions and identify solutions which work if the political will exists.

3. PRIVATIZATION

3.1 COMMON THEME

A common theme is apparent in the telecommunications service industry of some of the most advanced industrialized countries, newly industrialized countries (NIC's), developing countries heading that way and several of the Communist and recently Communist countries now emerging into the World Economy. That theme is privatization.

3.2 FORMS OF PRIVATIZATION

Privatization is taking one of a number of forms; some possible because of the large and sophisticated market for the services while others are dictated by restricted availability of resources or political and economic constraints. The traditional view that telecommunications cannot be entrusted to the private sector, and far less the foreign investor, is being challenged in many developing and industrialized countries alike.

The importance of a good telephone service to economic growth in developing countries is becoming part of accepted wisdom by politicians and bureaucrats alike. Recent research (Table 1) has demonstrated a remarkable correlation between economic growth and improved telecommunications adding to the evidence from the growing number of countries which have taken the plunge. That ultimate step to full private sector and foreign participation still eludes many Governments, giving rise to a wide range of structures all aimed at the same ultimate goal - accelerated improvement in the quality and quantity of telecommunications service available.

The structures considered in this paper are:

- Fully Privatized Operation (BOO)
- Franchised/Licensed Joint Venture (JV)
- Build, Operate and Transfer (BOT)
- Build, Transfer and Operate (BTO)

and an attempt is made to compare the implications of these for the country as a whole and the investor.

TABLE 1 PER CAPITA GNP AND TELEPHONE DENSITY
OF VARIOUS COUNTRIES
1987

Country	Per Capita GNP ($)	Telephone Density (Main Lines per 100 inhabitants)
Switzerland	27,520	53.51
Japan	22,050	40.34
Norway	21,450	46.51
Denmark	21,070	52.87

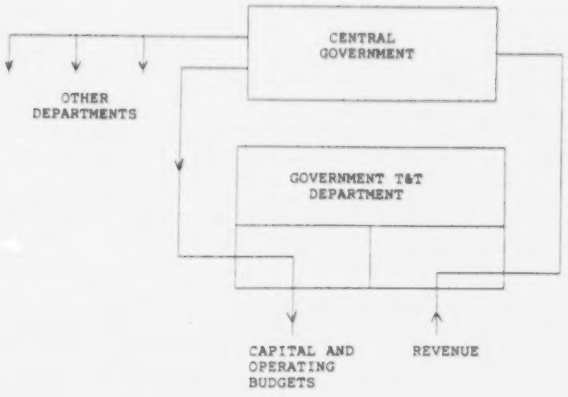
4. TELECOMMUNICATIONS INVESTMENT - THE NEED FOR CONTINUOUS AND GROWING INVESTMENT

Telecommunications demand, particularly in developing countries is of two forms: declared demand and latent demand. Once the network development accelerates and begins to satisfy the declared demand, so the latent demand manifests itself. People who had not even bothered to apply for service, now do so. The growing number of subscribers makes the service more useful and it attracts evenmore customers for this reason. The benefits which even the smallest private industrial, commercial or farming business enjoy from the service means that their peers must seek the same advantage to allow them to compete. The organic growth we are all familiar with has then begun. Unlike many manufacturing and infrastructure investments such as factories, bridges, roads or ships, telecommunications demand a continuing and, usually, growing level of investment year by year. The largely 'upfront' investment profile of these other industries cannot apply to telecommunication operation if demand is to be met and the advantages of a constantly changing technology are to be secured.

5. LINKING REVENUE GROWTH TO INVESTMENT

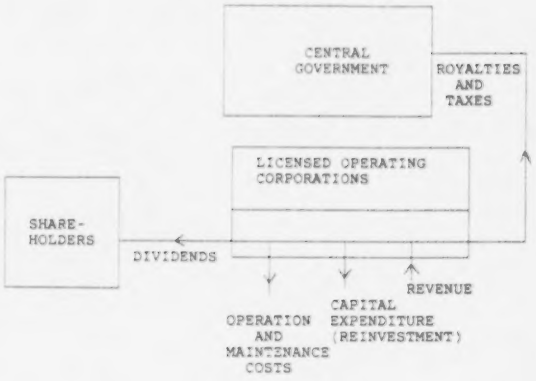
One of the major benefits of 'privatization', in common with 'corporatization' is to enable the growing revenue from the improved facilities to be used to fund further expansion and improvement. The days of Government T&T departments struggling with insufficient budgets while their revenues disappeared into central coffers are fading (Figure 1).

Figure 1 CENTRAL GOVERNMENT ACCOUNTING



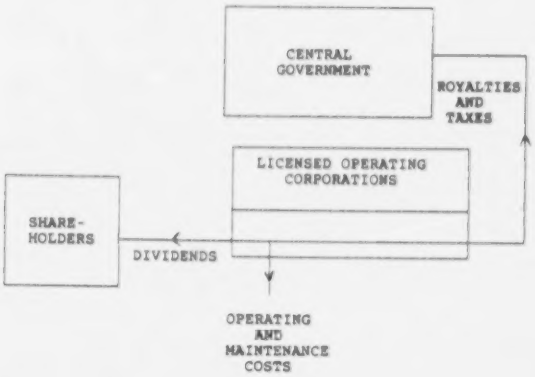
Care is needed however to ensure that the structure adopted for privatization does produce the same result a few years down the line, without losing the momentum of the early growth and improvements in service. (Figure 2, Figure 3).

Figure 2 TELECOMS LINKAGE



The linkage for a private sector bridge or road, involving an "up front" investment but no re-investment differs fundamentally from the above model for telecommunications, viz:

Figure 3 BRIDGE/ROAD LINKAGE AFTER INITIAL INVESTMENT (BOT, BTO STRUCTURE)



If the structure of privatization of telecommunications encourages or makes necessary this latter form of linkage between revenue and expenditure with no re-investment in capital expenditure then the early improvements will not continue.

6. TECHNOLOGY CONSIDERATION

Most countries are now embarking on digitalization programs. Macau is the largest network to achieve 100% digital operation as a result of a decision by the Government only ten years ago to bring private and foreign investment into a Joint Venture. More recent technical innovations in Macau, including a Managed Data Network and cellular mobile services emphasize the change from a cash-starved Government operation in 1981 to one, constantly incorporating new developments, continues. The enlightened Government is now re-negotiating the initial agreement with the Joint Venture shareholders (Cable and Wirleess, CPRM, CITIC and its own T&T Department) so that investment conditions will encourage this to continue even though the original contract still has another ten years to run.

Technical change will not stop and is not even showing any signs of slowing. Dramatic improvements in transmission, switching and software fields can be expected in the next 10/20 years which could make current facilities as old hat as paper/lead cables and Stowger exchanges are now. Developing countries are today urgently seeking to expand the quantity of their telecommunications to bring service to more people and stimulate economic growth in order to and become NIC's. The NIC's of tomorrow will need just as urgently to keep up with technological advances, and the new services these will bring, in order to remain competitive in the international market place. The implication of this for the structure of privatization, in fact adds to the need to find a formula which encourages re-investment and continuous evolution of the network as well as meeting the inexorable growth of demand for service.

7. EVOLUTION OF PRIVATIZATION

Several evolutionary paths can be traced and these depend more or less on how bold the Government concerned is prepared to be in moving from the common starting point of a Government T&T Department monopoly.

T&T Dept ---> State Corporation ---> Joint Venture (Government/Private).
Example: Jamaica.

T&T Dept ---> State Corporation ---> Full Privatization.
Example: New Zealand, UK.

T&T Dept ---> Partial Privatization of some sectors.
Example: Tonga (International), Pakistan (Cellular), Thailand (VSATS).

Supply Contracts ---> BTO.
Example: Vietnam (International), Thailand (Cellular, Paging).

Supply Contracts ---> BOT.
Example: Indonesia (Local Telephone)

T&T Dept ---> Joint Venture.
Example: Macau, Solomon Islands, Vanuatu.

In fact many of the JV's involve some provisions of a BOT, the main difference being in the "intention" of the agreement and the transfer conditions. In a JV, Government often reserves the right to buy out the private sector/foreign partner at a fair price (often net book value) after some minimum period. This is a partnership which can be terminated. The BOT may have a similar terminal payment although more commonly transfer of the assets to Government is at a specific time without compensation. In this case it is just a toll road which may be operated by the private investor for a fixed period to recoup his up front capital expenditure and then the road becomes to Government property. It is clear that BTO and BOT are really mechanisms for selling assets to Government rather than true involvement of the private sector as a long term investor. In this respect they represent only a change in detail and timescale from the traditional role of the supplier, to one who takes on the additional responsibility of an operator for a period to complete the sale process.

8. NEED FOR LEGISLATIVE CHANGE

All countries now seeking the benefits of Privatization in telecommunications started with laws allowing only the Government itself to provide service to the public. These laws are an accident of history but in many cases are still standing in the way of the real benefits of Privatization. Joint Ventures usually require a change to the law even where government has a majority shareholding. Full Privatization always does!

Changing the law may be difficult, particularly in Communist countries where the separation of economic and political reform seems to converge again on this issue. New legislation always involves the total monopoly of the Government department changing although often the JV, which Government can still control, often maintains this monopoly for several years. BOT and BTO arrangements can be "fudged" to be consistent with the old laws by saying the temporary, private sector operator is acting as an agent of the Government which itself retains the monopoly. This fudging always restricts more or less the commercial operation of the service and inevitably places a constraint on ongoing investment. In reality BOT and BTO usually mean that Goverment's day to day control is lost but the private operator is forced to squeeze the maximum return from his initial investment with minimum re-investment particularly in the latter part (probably half) of the immutable operating period. Long term investments and technical innovation in this period would be commercially impossible.

9. COMPARISON OF STRUCTURES

9.1 FULLY PRIVATIZED OPERATION

This is the boldest step leaving government with regulatory control only over the operation (except in cases of national emergency etc). The operator is fully motivated to re-invest for commercial reasons and needs to perform well enough to secure licence renewal. May be in the form of JV between private sector and foreign investor to bring in outside finance and expertize. Often combined with competition in many telecommunication market sectors while continuing the natural monopoly of the basic network services in all but the largest and most sophisticated countries (US, UK, Japan).

9.2 JOINT VENTURE

May be between private and public sector or either and foreign investor. In developing countries the latter bringing rapid overseas investment, training, transfer of technology and committed management experience. The ongoing nature of the partnership, with reviews/extensions built in ensures long term investment, technical innovation in everyone's best interests and tailored to economic, social, security, legislative and political conditions by nature of JV agreement. Organic growth encouraged by commercial, social and economic factors.

9.3 BOT

Revenue from operation used to pay for specific equipment which will be provided as quickly as possible to maximise revenue during fixed operating period. Operator has no real interest in what happens after his operating period. Investment group often includes supplier as means of financing his equipment sale. Government eventually gets equipment which may be obsolete or approaching it by that time <u>but</u> without actually paying money. Investor can use normal depreciation if net book transfer is provided for. If there is zero compensation at transfer, the resulting accelerated depreciation must dampen re-investment eventually to zero, make financing impossible in later stage and impact on tariffs and taxes. Ideally the operator should finish the period by connecting the last possible new customer on the last day using technology which has been fully depreciated and therefore due for replacement.

9.4 BTO

This has most of the features of BOT but presents an accounting and legal problem for many foreign investors who are operators. The assets are transferred to government at once, before operation starts. The operator then has on his books a "right to use" the assets rather than title to them. In practical terms it may be the same although BTO's often involve restriction of the freedom of investment decisions by the operator making the relationship even more like an equipment supply contract with long term, high risk financing. Back at the ranch, in the foreign operator's corporate headquarters, some legal gymnestics and creative accounting are needed to record for posterity, and more particularly for the shareholders, what the company got for its money.

10. HOW DO THEY MEET OBJECTIVES

This paper aims only to compare how well the various structures meet the objectives which any particular Government may have relative to the above considerations. No conclusions are possible as they will depend on the weighting of the objectives in each individual case.

The objectives assume a Government T&T Department or State owned Corporation starting point.

The Revenue accruing to Government is relatively independant of the structure and is decided by the details of the individual agreement and the degree of commercial success achieved.

From the point of view of a foreign operator the Joint Venture and Full Privatization are generally more acceptable; the preference between these depending largely on individual corporate background. Some US companies seem to prefer 100% private ownership while Europeans like Cable and Wireless look for Joint Ventures with Governments but there are almost as many exceptions as examples of these gross over-simplification.

Following the examples of various motoring magazines and consumer publications, a "Buyers Guide" (Table 2) is offered in the hope that it may encourage an ongoing discussion of the subject in "consumer countries". The greater the number of stars, the more the objective concerned seems to be met! Those structures involving long term private sector and foreign investment are clearly better in meeting the objectives related to service, demand and technology. The BTO/BOT formula shows advantages in avoiding regulatory change and retaining Government influence or control. The latter is shown as much less significant when it really matters in terms of National Emergencies and Security.

TABLE 2 BUYERS GUIDE TO TELECOM PRIVATIZATION

	Ease of Regulatory Transition	Ensure Ongoing Investment	Avoid Technical Obsolescence	Encourage Foreign Investment	Long Term Investor Commitment	Reactive to Socio-economic Needs	Government Influence Ongoing Investment	Government Retain Daily Control	National Security Guarantees
FULLY PRIVATIZED (FOREIGN UPTO 100%)	★	★★★	★★★★	★★★★	★★★★	★★★	★		★★★
JV PRIVATE SECTOR / FOREIGN	★	★★★	★★★★	★★★★	★★★★	★★★	★		★★
JV GOVT / FOREIGN	★★	★★★★	★★★★	★★★★	★★★★	★★★★	★★★	★	★★★★
BOT	★★★			★	★	★		★	★★
BTO	★★★★		★			★	★	★★★	★★★★

11. CONCLUSION

There is no conclusion offered - only an observation. If the outline of structures and the checklist stimulates productive discussion in the corridors of power of some developing countries, NICs and would be NIC's, to time spent in preparing the paper and reading it will be more than justified.

And the observation:

For many Governments the bold step to Telecommunications Privatization is a difficult one to take. None who have taken it have had reason to regret it but it is worth devoting the time and honesty to take it properly. Fudging the step now will stare up disillusion and lost chances for which history will be the judge.

THE NORTH PACIFIC CABLE

Charting a Course for International Alliances

David Walker
Vice President, Engineering and Operations
Pacific Telecom Cable, Inc.
Vancouver, Washington

1. ABSTRACT

With proper structuring, an understanding of the business culture of other nations and a willingness to negotiate on critical issues, international alliances can be successfully implemented. The North Pacific Cable project, an alliance between American, British and Japanese interests, is a real world example of how such alliances are formed and how they function.

2. INTRODUCTION

In 1986, a strategic alliance was formed by American, British and Japanese parties to construct the North Pacific Cable. NPC is the first direct trans-Pacific fiber optic cable link between the U.S. and Japan and the highest capacity cable in the Pacific. Through its Alaskan spur, it also provides the first fiber link between Alaska and the contiguous 48 states.

NPC's founding parties are Pacific Telecom Cable, Inc. (U.S.), Cable and Wireless plc (U.K.) and International Digital Communications Inc. (Japan). Since the establishment of the project, NPC's owners have expanded to include 34 carriers and administrations from 21 countries. Approximately 50 percent of NPC's U.S. - Japan capacity (1,260 Mbit/s) and all of its Alaska - contiguous U.S. capacity (420 Mbit/s) has been acquired by these organizations. The cable was commercially activated May 10, 1991.

While the 5,200-mile NPC represents a successful alliance between firms of three nations, the road to success was not always smooth. The real world experiences of NPC should prove useful to others seeking to establish joint ventures or strategic alliances for international projects.

3. ORIGINAL OWNERSHIP AND BACKGROUND

Original ownership shares in the Japan end of NPC were held 70 percent by International Digital Communications Inc. and 30 percent by Cable and Wireless plc. This ownership split was a result of nine months of negotiations. During this period, the total cable capacity, the expectations of Japanese traffic (terminal vs. transit), and the needs and risks of such an ambitious project were discussed and negotiated extensively among the three parties and with Japanese regulatory agencies.

IDC was formed in 1987 to compete with KDD, Japan's then monopoly international carrier, much as MCI and US Sprint compete with AT&T. Some 144 companies, including 39 of the top 50 most profitable firms in Japan, are shareholders in IDC. C. Itoh, the largest Japanese trading company (with more than $150 billion in sales), Cable and Wireless, Toyota and Pacific Telesis are the largest shareholders in IDC. American participation also includes Merrill Lynch.

Original ownership of the U.S. end was 100 percent by Pacific Telecom Cable, Inc. PTC, in turn, is owned 80 percent by Pacific Telecom, Inc., the telecommunications subsidiary of PacifiCorp, and 20 percent by Cable and Wireless.

For the funding of NPC, owners of the U.S. end contributed 56.63 percent of the capital while the Japan-end owners contributed 43.37 percent. These percentages evolved as a result of two years of negotiations.

The length of time it took to establish the ownership shares of the Japan end and the funding of NPC illustrates the importance of patience in negotiating international projects. But another important lesson in the success of a project is the ongoing willingness of the parties to put aside their respective ownership positions during ongoing negotiating sessions. The reason why each partner must have an "equal voice" regardless of their financial position will be covered later.

But there is more than funding to assure the success of a venture. In the case of NPC, each of the three parties brought something else to the table.

IDC, in addition to its funding capability, provides a needed presence in Japan, while its shareholders comprise a large customer base for service on

the cable. Each of its shareholders was chosen in part because of its international telecommunications requirements.

C&W is a worldwide recognized carrier. For example, C&W runs the international telecoms services for Bermuda, the Bahamas, Hong Kong, Bahrain and numerous other locations. Its Mercury Communications subsidiary competes with British Telecom in the United Kingdom. C&W is also a leader in procuring and installing submarine cable systems through its subsidiary, Cable and Wireless (Marine), and in operating submarine cable systems through a number of its subsidiaries. C&W (Marine) has the largest cableship fleet in the world, currently numbering 13 vessels. This compares to the three ships (plus one under construction) of AT&T. Many C&W cableships are equipped with remotely controlled submersible vehicles for cable burial and maintenance.

PTC in the United States obtained the U.S. landing license from the FCC. As one of the nation's largest non-Bell telephone companies, PTC's parent PTI contributed telecommunications expertise to the project.

Together, the founding parties have shared not only in capital but in a willingness to bear the risk of a new venture.

4. MAKING AN ALLIANCE WORK

Several things combine to make an international alliance work. First, a successful alliance presumes opportunity. In the case of NPC, the opportunity was a need for services not being met by other suppliers. This need was recognized by the Federal Communications Commission in granting PTC a license to land the cable in the U.S. Benefits cited by the Commission include:

-- service on a non-common carrier basis
-- assurances of availability and price
-- custom-tailored service arrangements, and
-- encouraging new service offerings.

NPC contributes to service reliability in the Pacific by providing alternate routing for other systems planned for installation in the 1990s. This deserves additional comment.

Although trans-Pacific traffic growth was booming at the time NPC was first envisioned in 1985, there were those who argued that the planned HAW-4/TPC-3 cable would satisfy demand until the year 2000. These predictions were used by Japan's telecommunications industry and regulatory powers to delay by more than nine months granting IDC its license to land and operate NPC in Japan. The forecasts in traffic growth by NPC's owners indicated otherwise and have since been vindicated by the announcement of TPC-4 and TPC-5 as common carrier cables.

Opportunities for successful ventures are also enhanced when high-quality services are offered at a lower price. NPC's high capacity and direct routing between the U.S. and Japan has resulted in circuit costs some one-third those of HAW-4/TPC-3.

Another ingredient to a successful venture is commonality of purpose. The venture must mesh with the business requirements of the participants. Otherwise there is danger that commitment may abate.

A new trans-Pacific fiber cable was a good "fit" for the long-term goals of each of the three founding parties. For IDC, a newly licensed Japanese international carrier, it is a means of using its own facilities in competing with the other two Japanese international service carriers.

For Cable and Wireless, NPC is an ideal way to extend its "global digital highway" across the Pacific to connect its markets in the Far East with those in the U.S. and Europe. In particular, C&W envisioned a London-Hong Kong fiber service. NPC is the last link in this portion of their digital highway.

Pacific Telecom views NPC as a means of providing a fiber route between its Alaskan carrier, Alascom, Inc., and the lower 48 states, and to expand its business beyond the services of its many local telephone companies.

5. THE COLD WATERS OF REALITY

These ingredients - bringing something to the table, serving the market, and commonality of purpose - are classic business school requirements for any alliance. But what is often missed in the classroom can provide some surprises in the real world. Let's now turn to some difficulties to be aware of.

My last sentence is an example. It's "American English." In "English English," a sentence would never end with a preposition. The NPC project blends Japanese, American English and English English -- a good environment for language barriers.

When East and West meet in joint

ventures, patience and understanding are essential. The varied cultures mean different ways of addressing and resolving problems, of running meetings and negotiating with contractors. These differences are compounded when negotiations are conducted over 18 time zones. Participants must plan and budget for extensive and expensive travel associated with attendance at the requisite international meetings.

For a successful multinational project the American inclination for getting it done "now" must take a back seat as the time required for decision-making is extended. Similarly, the American fondness for logical analysis and fancy footwork must be tempered to accommodate the Japanese desire for harmony and trust, and the British emphasis on the proper approach to resolving any problem.

Given these differences in national character, international joint ventures might better be called joint compromises. The ability of participants to be ready and willing to compromise for the success of the overall project is something that can go against the grain of some hard-negotiating companies.

NPC is a success because in each instance where there were differences of opinion, the founding parties were able to reach consensus. Consensus building must have nothing to do with the relative financial input or ownership percentage of the parties, otherwise those with a smaller share will soon lose interest. This concern was touched on earlier in discussing the impact of ownership positions on managing an alliance. Anyone considering an international alliance must be willing to "win some/lose some" for the overall success of the project.

Lastly, don't be surprised if you have problems with regulatory bodies and competition. In addition to its licensing delays, IDC faced another difficult period when the Ministry urged that it unite with ITJ, the second new international carrier licensed in Japan, so that KDD would have but one competitor. Pacific Telecom Cable was subjected to several cautions by the FCC concerning the selection of vendors for NPC components and installation. While there may have been good reason for these cautions, nevertheless they required substantial additional effort to ensure compliance.

6. STRENGTHENING THE TIES

Strong international relationships are particularly important for multinational ventures of long duration such as a trans-oceanic cable with a 25-year service life. The harmonious environment built over the past five years was instrumental in helping the original three owners quickly respond to two service outages early in the life of the cable. But more importantly, earlier efforts by NPC's original owners to formulate restoration procedures to respond to a cable failure meant that traffic was restored via satellite in the unprecedented time of just over one hour following both outages.

And as a final measure of success, the original three founders of NPC have agreed to continue their relationship by forming another strategic alliance to construct and operate a new cableship for the purpose of maintaining the NPC system. The new ship will be berthed in the Pacific Northwest. While its primary purpose will be to serve the needs of NPC, it could also be made available for other services in the Eastern Pacific.

7. CONCLUSION

International alliances can be successful if there's patience, understanding and a mutual respect for cultural differences; if consensus can be reached despite individual interests of the parties, and if the project fits into the participants' business plans. The road to success may not always be smooth, but when success is achieved, it opens the door to new opportunities.

Graphical Communication Network Simulator

H. W. Chan
Department of Computer Science
University of Hong Kong
Hong Kong

Abstract

A new approach for network simulation based on graphical representation of network topology and its protocols has been implemented on X window. The protocol represented by Petri nets with extended features can be drawn to specifications. Service discipline and routing strategy can be entered by pull down menus. A simulation model is automatically generated from the representation and simulation results are displayed in graphical form.

1 Introduction

In a computer communication network (e.g., X.25), users share dynamically a distributed pool of resources such as buffers, communication channels [1]. Mathematical analysis with simplifying assumptions has been found useful to study different routing and flow control schemes [2]. However, assumptions such as unlimited nodal buffers, exponential packet length and probabilistic routing are not realistic. In fact, nodal buffers are not infinite, and limited buffer size as well as buffer allocation discipline among competing users will affect performance characteristics such as delay, throughput, queue length and processor's utilization. Therefore simulation models are often used to study a more realistic situation where fixed packet length and status-dependent routing are used.

Traditionally, simulation languages [3] or simulation packages [4] may be used to construct models for specific applications. However, the designers are not free from transforming their conceptual network model to the detail code of the simulation language. In addition, only statistics in numerical form are available at the end of the simulation run and the output is often hard to interpret. Some efforts have been made toward graphical interfaces which are built ad hoc on top of the underlying language [5], but they are neither efficient nor user friendly. Operationally one has to follow very closely the underlying language construction. Subsequently the designer is still burdened with providing all the operational details.

A graphical approach for network simulation has been designed for users to specify the network requirements in a much easier way than using programming languages. In order to reduce the difficulties associated with modeling a complex system such as a communication network, three major program modules, namely topology, nodes, and protocol modules are used to define the network. The topology module describes the physical layout of the network as well as the physical transmission characteristics of the medium. The node module specifies the attributes of the devices (e.g., switching centers) in the network. The protocol module specifies the rules for communication on each link. Additional modules, namely simulation core and statistic control modules are provided to carry out the simulation and display the statistical results in graphical form.

The simulator supports process interruption and termination. With interruption control, users are free to examine the current status of the network during the simulation. The process can later be resumed. With termination control, the simulation process can be terminated at any time and the process control will be returned to the user interface.

2 Approach and Requirements

In this section we describe the requirements for the simulator and the approach we take to reduce the difficulties associated with modeling such a complex system.

The simulator should allow heterogeneous jobs in the system i.e., each class of jobs has its own set of attributes. Routing of these jobs depends not only on the topology, but also on their attribute values. The simulator should be able to simulate two types of network simulation, namely open network where there is no limit on the number of jobs created [6] and closed network where the number of jobs in the network is fixed [7]. Jobs are created from the source node and circulated in the network in accordance to the routing strategy. Measures such as total delay and throughput should be available at the end of simulation runs. Statistic on nodes, links and queues e.g., their utilization and queue length should be readily obtained.

2.1 Topology Module

The topology of a network defines the way in which information is propagated on the transmission medium. The network is modeled as a set of resources (e.g., communication links, buffers) and a set of jobs (e.g., packets, acknowledgment, messages, etc.) interacted in certain ways. The actual physical layout of nodes, links, together with their characteristics has to be defined. Therefore the topology is drawn as a set of junctions

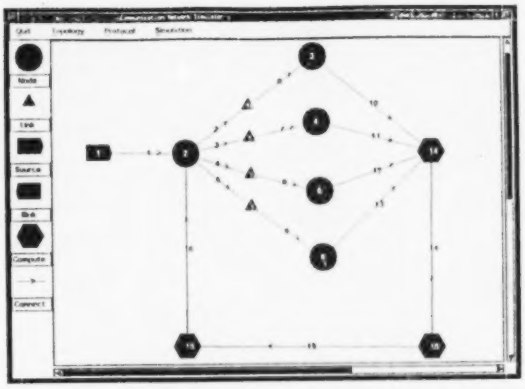


Figure 1: topology specification

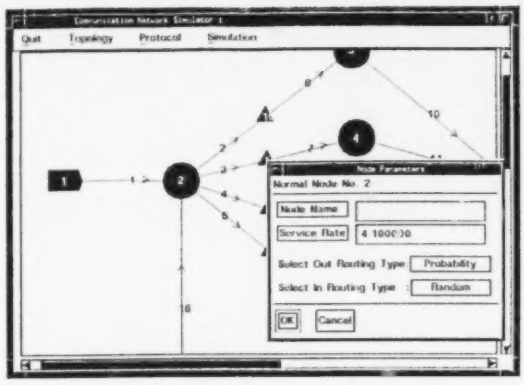

Figure 2: node parameters

(nodes, links, sources, sinks), and a set of connectors which are directional arcs that originate from one junction and destinate to another junction (Figure 1).

2.2 Node Module

After the topology has been defined, the characteristics of the devices must be specified. The following list of parameters for the nodes may be given:

- name and the service rate (Figure 2)
- capacity of the incoming and outgoing buffers with their corresponding queueing discipline
- strategy of choosing an incoming buffer which may be random, probabilistic, prioritized, status-dependent (e.g., current queue length or queueing time)
- strategy of choosing an outgoing buffer which may be random, probabilistic, prioritized, status-dependent (e.g., current queue length) or the status of the target node connected with each outgoing buffer
- job attribute routing, explained in section 4.1.2

2.3 Protocol Module

In specifying a communication protocol on a link, a graph-based model [8] is used in the simulator. This is the Petri net model which composed of a set of places possibly with a token in it, a set of triggers, and a set of directed arcs. A place represents a state and a trigger represents a transition of the system. The arcs connect places and triggers. Tokens are located at a place when it is active. Multiple places leading into one trigger represent a boolean AND condition. A trigger has one or more input arcs, coming from its input places, and one or more output arcs, going to its output places. A trigger is enabled if there is at least one input token in each of its input places. Any enabled trigger may fire denoting an occurrence of the transition, removing one token from each input place and depositing a token in each output place. If two or more triggers are enabled, any one of them may fire.

Petri nets provide a means of describing a protocol. However, several modifications to the basic Petri net are needed to model additional features such as delays in communication network. First, in our specification, the role of the token has been enhanced by incorporating a list of attributes associated with each token for identification. Second, basic Petri nets have no time delays associated with the trigger. In a discrete event simulation, scheduling events after a specific time delay is essential so delay trigger is introduced to model time delay. When a token enters a place connecting to the delay trigger, it will be delayed for the specified time period which may be deterministic or stochastic. Some other transitions may cause the firing of the delay trigger. Therefore this delay time can also be interrupted by another place if both places lead to firing of the trigger. Third, Petri nets are not designed to represent layers of protocol in the OSI reference model. In the basic Petri net, all elements of the protocol must appear in the same network diagram. In order to associate a protocol with a link, two predefined places SOT and EOT are used in all protocol specifications. SOT represents the start of transmission and EOT represents the end of transmission. An example is given in Figure 3.

In basic Petri nets, when a trigger is fired, the tokens from the input places are removed. One token is sent to the trigger, and the others are destroyed. There is no facility to specify which token will pass to the trigger. Information stored in the attributes of a token can be lost if the wrong token is sent to the trigger. Therefore a flag is set to indicate where the information are stored in that place. Hence, when a trigger is fired, the token from the input place having the flag set would be stored and then passed to the output place with its flag also being set.

After the protocol has been drawn, the parameters of the delay trigger such as the delay distribution and parameters of the places such as the flag to indicate

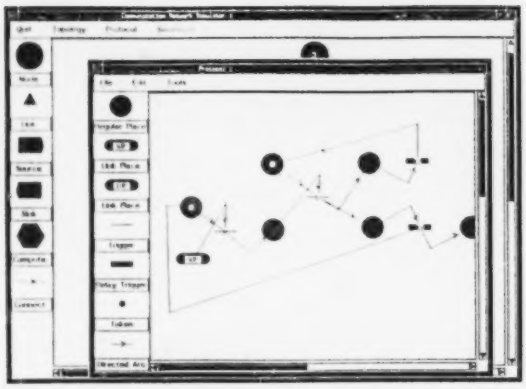

Figure 3: Petri net

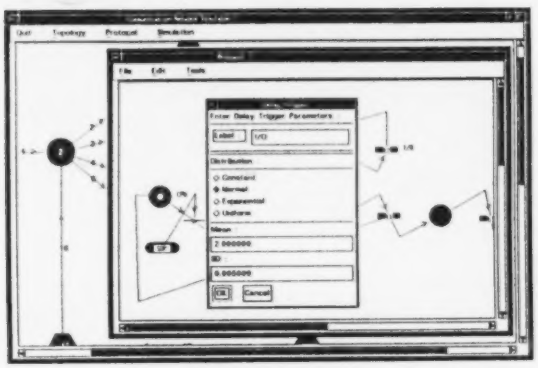

Figure 4: Delay trigger

whether it is needed to store the information of the token must be given (Figure 4).

2.4 Simulation and Statistic Control Module

The simulation should be run for number of times to provide statistical analysis of the output data. Users are free to input any number of batches by which each run of the simulation will be divided [9]. Both the transient-state and the steady-state behavior of the simulation can be observed on the statistic output graph. Users should also be able to give any level of confidence to the statistic charts and the variance of the data collected during the simulation can then be observed.

3 User Interface

3.1 Design of the User Interface

It is easier to define the topology layout in graphical form by selecting proper icons using the mouse. On the other hand, it is appropriate to enter numerical values such as probability distributions by using menu. Therefore an interface with the following features has been constructed:

3.1.1 User friendly

Topology and protocol specification are better expressed in graphics while statistical results from simulation are better expressed in charts instead of numerical figures. These services could be provided by popup menu activated directly by pressing a particular icon. Number of level and amount of information on each menu must be minimal for efficient operation otherwise the user may have to select from a long list of functions. Therefore appropriate grouping of functions are provided so that primary data can be input. In addition, default values has been defined for some commonly used values, e.g., single server at the node. Option menu are also available for the user to recall data values. Resizable previewers and scrolled bars are provided to help users access particular drawing regions on the screen.

3.1.2 Minimize input errors

Error menu are prompted whenever errors are detected. The error message indicates the nature of the error and any correction needed to be done. A logical usage of the functions is enforced e.g., drawing mode is not mixed with input mode, to minimize input error. Another feature is to deactivate those items that are not currently meaningful.

3.1.3 Use appropriate colors/ icon shape/ operation appearance

Menu colors for topology and protocol input are different such that distinct multiple menu could be seen on screen. Also background color for the drawing area is different from that for the pulldown menu for easy identification. Different icon shape related to its meaning is used. Rubber band lines are used as an indication of a not yet finished line. This function allows users observe the partially finished line e.g., turning points in the Petri Net model for the protocol input, before deciding on the final drawing.

3.2 Construction of the User Interface

3.2.1 Topology Input

If an unselected icon is picked from the icon list, it will be inverted in color to indicate that it is chosen. If a previous selected icon is picked, it will return to its normal color to indicate that it becomes unselected. To achieve this, both the previously selected icon index and the currently selected icon index must be stored in order to give the necessary effect. To make the number of icons available on the list flexible, all icon options are implemented by array manipulation. A direct index can be used to access an indexed icon.

To draw an icon on screen requires two steps, namely direct the icon to the desired location and draw the

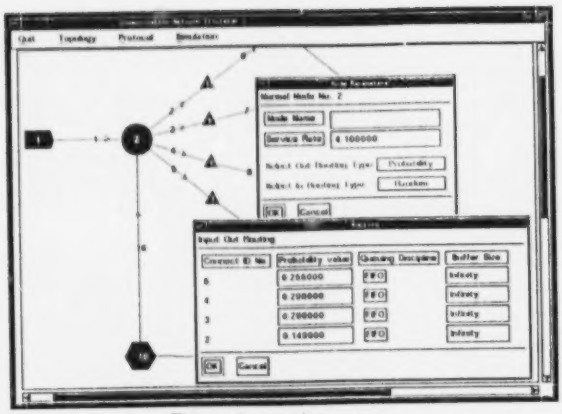

Figure 5: routing menu

icon. The method used is to operate in an exclusive-or mode (XOR) so that two consecutive drawings will cancel each. This is particularly suitable for simulating the effect of a moving icon. In case of line drawing, particularly the directed arc in protocol, flags are used to denote different cases for optimal effect.

Redrawing requires possibly a large amount of bitmap information stored on the drawing area to be refreshed. Internal data structure is traversed and drawing area is updated. Size of icon can also be changed to meet the user's requirement. This is achieved by giving a ratio for each icon drawing function.

3.2.2 Data Input and Display

Menu for input are constructed from a set of widgets on X [10]. They are customerized according to specifics, e.g., for the routing menu, the number of row corresponds to the number of outgoing/incoming links while the number of columns corresponds to the routing type (Figure 5). Certain fields on the menu will be deactivated to minimize user error if data has to be entered in sequence. An intensive error checking is imposed upon the data items, e.g., data type, invalid sequence of operation, inconsistence between data items. The user is then allowed to make corrections. To protect accidental erasure of important data, warning or confirmation menu are prompted.

4 Implementation

4.1 Data-Building Module

Data-Building (DB) Module is a module which serves as a bridge between the user interface which is described in the last section and Simulation Core Module, the core for simulation. DB Module has three main components.

4.1.1 Network Topology

Network topology is consisted of source, sink, normal, compute nodes and link server (Figure 1). Connectors

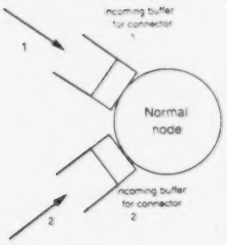

Figure 6: buffers for each link

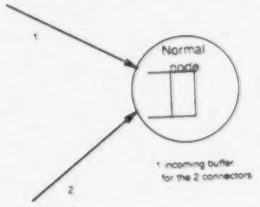

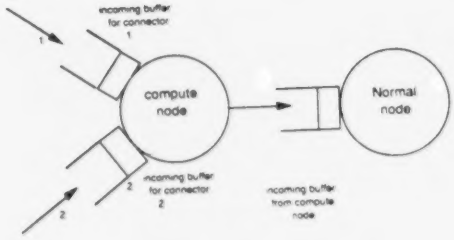

Figure 7: sharing common buffers

are used to connect a node with a link server. They connect source, normal or compute nodes to a link server and from a link server to normal, sink or compute nodes. Normal nodes correspond to switching centers and link servers correspond to transmission channels. The relationships between the nodes and the link servers are as follow.

- There is no incoming connector for source node and no outgoing connector for the sink node.
- There can be more than one outgoing and one incoming connector for the normal node and compute node.
- There can be only one outgoing and one incoming connector for the link server.

In our initial design, node buffers are associated directly with the connectors, illustrated in Figure 6. This shows that each connector has its own partition of buffers. However, the simulator is not able to simulate sharing a common pool of buffers. Therefore a compute node with zero service time is used to achieve sharing a common buffer pool as illustrated in Figure 7.

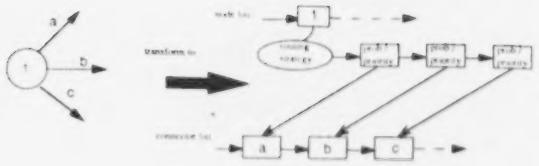

Figure 8: routing implementation

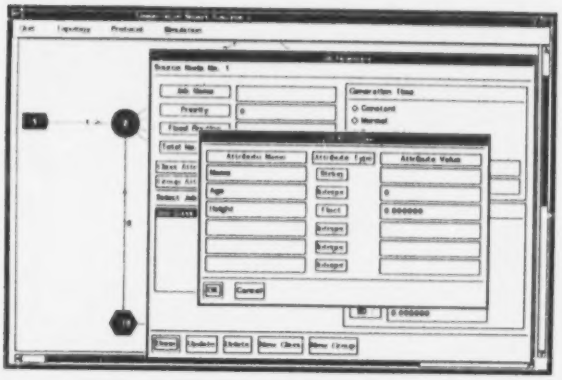

Figure 9: job's attribute

4.1.2 Jobs in the Network

Basically there are four types of routing strategies after a job has been served in a normal or compute node:

1. Random: each connector has equal probability of being chosen as an outgoing path.
2. Probabilistic: each connector is assigned a probability of being chosen for routing
3. Priority: each connector is assigned with a priority number. The connector with the highest priority is chosen. If the highest priority connector is full, the second higher priority connector is chosen and so on.
4. Current status: the connector selected is determined by the current status of the system, namely queue length of the connectors, queueing time and status of the opposite node on the connector. Its structure is illustrated in Figure 8.

A useful feature provided in the simulator is job's attribute routing where the routing depends on the job's attribute values. Jobs may be categorized into classes. Each class can have its own set of job attributes and a maximum of six attributes for each job class can be specified (Figure 9). For each attributes, three different types of value are possible, namely integer, float and string. For each job class, an independent set of conditions is used to determine its routing strategy. If each job class uses its set of attribute and attribute values

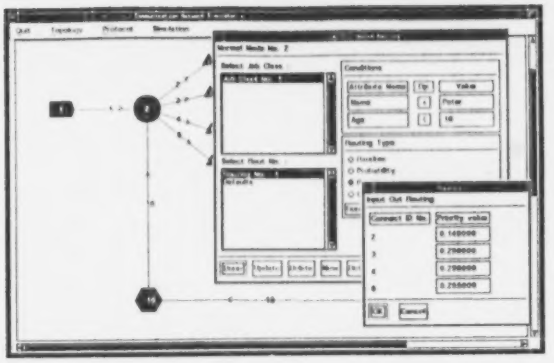

Figure 10: attribute routing

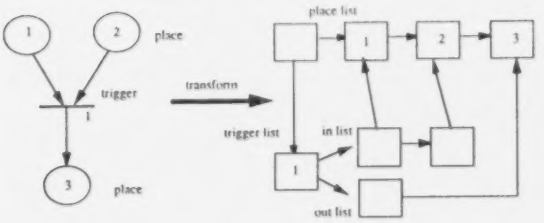

Figure 11: transformation of Petri net

for routing, then each member in the class must satisfy the same condition and follow the same routing strategy (Figure 10). If the job class is further classified into groups, each group can have different attribute values for the same set of attribute names. This implies that different groups within the same job class can have different routing strategies.

4.1.3 Communication Protocol

Protocols are described by Petri nets consisting of four components, namely places, delay trigger, trigger and directed arcs It is used to control the flow of jobs between two normal nodes. Places, triggers are represented by link lists while the arcs that directed in and directed out from the trigger are represented by an in- and an out- lists respectively. Figure 11 shows an instance of Petri net which is transformed into the corresponding link lists.

4.2 Interaction between User Interface and DB Module

The user interface passes information to the DB Module by a series of predefined function calls. For data input or figures drawn on the drawing region, the data has to be validated and stored into the corresponding structure. Five main function calls are provided by the DB Module:

1. Add node functions

When the user draws a node on the drawing area, the information regarding this node such as the x- and y- coordinates will be passed to the DB Module. The add node function checks the validity of the drawing (e.g., no overlap with other icons in the drawing area). After validation, the node information will be put into the corresponding structure. The data required by the node (e.g., service rate) will also be input by the function call.

2. Add connector functions

   The connector contains tail and the head coordinates. When this information is passed to the DB Module by the add connector function, the coordinates will be checked to determine whether they are within the neighborhood of some nodes. Whether the connector is connected with the nodes in a proper way (e.g., normal node cannot be directly connected to another normal node without going through a link server) will also be checked. After validation, it is put into the corresponding structure.

3. Add job functions

   The user interface can call the add job function to create a new class of jobs or a group of an existing class of jobs. The data required by the job class (e.g., generation rate and job size) are passed by the function call to the structures for jobs. If fixed routing path is given for the job, the DB Module will check the validity of the routing path. If the path is valid, it will be put into the corresponding structure.

4. Add protocol functions

   When the user draws a protocol model or loads a protocol from a file, the DB Module will build the corresponding structure. An independent protocol structure for each of the associated links will be reproduced. Furthermore, the add protocol functions consist of add place and trigger functions, and add arc functions. Both the add place and trigger functions, and the add arc functions which add directed arcs from the place to the trigger or vice versa are checked for validatity (e.g., it is illegal to direct the arc from place to place or from trigger to trigger) before putting into corresponding structure.

5. Add routing functions

   After the topology of the network has been defined, the routing strategy has to be specified together with other information (e.g., probability value/ priority value for each connector). It is simple for four basic routing strategies. For attribute routing, both the routing and the input conditions have to be checked for correctness. For example, the data type of the job's attribute has to match with the type of the input data.

Input and default data values can be shown by pop up menu from the user interface which calls the DB Module for the information. Again the user interface uses a series of predefined functions available in the DB Module. For example, if the user wants to display the service rate of a normal node, the function will search for the right node and gets its service rate.

Thus, DB Module provides a library of functions for the user interface to utilize. In this way independence between the DB Module and user interface can be obtained. The user interface module does not need to take care or even know about the data structure of the model. It only needs to call the predefined functions to build the data structure and gets the data value. The building and retrieval processes which are the main functions of the DB Module are completely hidden from the user interface. Therefore modification of the data structure is transparent to users.

4.3 Interaction between DB Module and Simulation Core

DB Module creates the event list of jobs for the simulation. The list contains the job generation event and the end event of simulation. This list is passed to the simulation core which manipulates the data structure during the simulation process. Additional interaction involves two separate text files, namely network and protocol files. Network file contains information for node, connector, job and attribute routing of the network. Protocol file contains information for places, triggers and directed arcs of the protocol. Therefore, performance of different protocols can be compared by loading the protocol models for the same network configuration. DB Module is responsible for saving and loading of these network and protocol files.

In summary, DB Module is a module that communicates with both the user interface and the simulation core. The module contains a library of functions for the construction of network and protocol data structures which are hidden from the user interface. The module also provides functions to load and save information files which could be reused in different network and protocol configurations. This collective set of functions is designed such that it is not built around any particular program design. Therefore future enhancement of the system will not be confined by the design.

5 Statistics Collection

During simulation, the system has random inputs consisting of sequences of random variables with specific distributions. These variables represent the probablistic nature of the system, such as job generation time, node service time, etc. Correspondingly, random outputs consisting of sequences of variables such as node utilization, throughput of the system are characterized with an unknown distribution. The characteristics of these output distributions have to be estimated.

The user is mostly interested in the steady state results of the simulation. In this case, the simulation

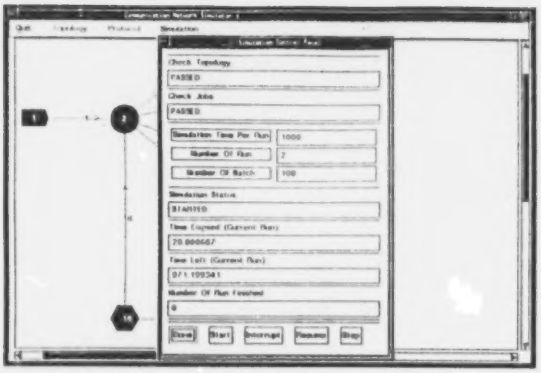

Figure 12: simulation panel

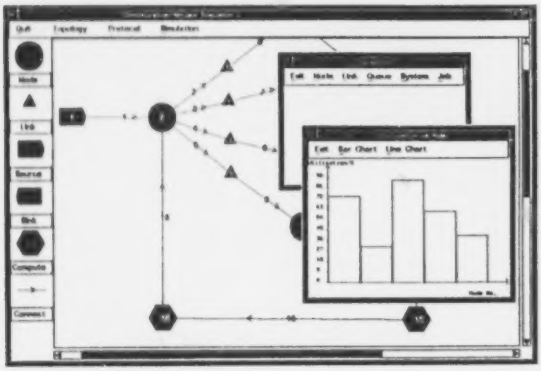

Figure 13: bar chart and line chart

must typically be run for a long period when performance measure will be collected and analyzed such that effects of the initial state on the performance measure are negligible. Moreover the user is allowed to specify the number of run for each simulation. A single run of simulation is divided into N equal time intervals given by user. Replications are made by using nonoverlapping independent streams of random number, so that classical statistical analytical methods could be applied (Figure 12).

During simulation, statistics are stored in the data structure. The statistical graphs can then be plotted by getting the information from the data structures. Ten statistic output results are available from the simulator. They are presented as bar chart or line chart illustrated in Figure 13. At most four different type of graphs could be displayed on the screen simultaneously, so that comparison could be made. The size of the graphs could also be adjusted by resizing the drawing area. All statistic outputs are handled mainly by three routines, namely, plotting the x- and y - axis, bar chart and the line chart. The routine rounds off the data by two significant figures. An additional routine is used to plot the confidential interval for the system throughput.

Nearly all the output graphs are plotted in ratio instead of plotted by absolute value and eleven graphical statistic graphs are provided:

1. node utilization Vs normal node
   normal node utilization - node total busy time / total simulation time
2. link utilization Vs link node
   link utilization - link total busy time / total simulation time.
3. max queue length ratio Vs queue
   max queue length ratio - Peak queue length / queue size
4. min queue length Vs queue
   min queue length ratio - min queue length / queue size
5. average queue length Vs queue
   average queue length ratio - average queue length / queue size
6. max queue time Vs queue
   This is an absolute value not ratio graph.
7. average queue time Vs queue
   This is an absolute value graph.
8. system throughput Vs simulation time
   system throughput - number of job finished / number of job created

   Confidence interval can be computed if multiple runs are made for the simulation. If the simulation is run m times and each run is divided into N equal time intervals, m samples for each period of time could be obtained. Users can use this graph to determine the variance of each collected set of samples. This graph gives the overall system throughput which allows the transient portion and the steady portion of the system to be determined.
9. number of job delay Vs delay time
   number of job delay - number of finished jobs
10. job delay Vs delay time (for specific job class)
    In this graph, the result is plot for each job class
11. throughput for each job class Vs job class
    throughput for each job class - number of job finished for this job class / number of job created for this job class

Users can only roughly estimate the output values from the graphical outputs. So some important data values can be obtained from five data report files.

1. *node.stat* - reports the node utilization for each node
2. *link.stat* - reports the link utilization for each link
3. *queue.stat* - reports the maximum queue length, average queue length, minimum queue length, maximum queueing time, minimum queueing time for each queue

4. *job.stat* - reports the job throughput for each job class i.e., the number of job finished and number of job created for each job class

5. *logfile* - reports the absolute values of the graphical data consisting of the following statistics:

   - node statistic - statistic of total busy time and total idle time for each node, namely compute, source, link and normal in the network.
   - connector statistic - maximum queue length, minimum queue length, current queue length, maximum queue time, number of job arrival and average queue time for each queue in the network.
   - job statistic - total number of job finished, number of job created, number of job active in node and number of job queued in the network for each job class.
   - system throughput - the system throughput of the simulation in discrete time intervals (number of intervals is given by the user before the simulation)
   - time used - the user time, system time and CPU time used in the simulation.

6 Conclusions

We have designed and implemented a user friendly system interface for network simulation using mouse to input the communication network model on screen. Output will be displayed in color graphics. The methodology can simplify the design of a complex communication system with a high degree of flexibility provided by the graphical input approach. This will have a practical impact in shortening the design cycle, significantly reducing the time required to interpret the result. In addition, it reduces the time for debugging and testing of the model.

Future extensions can be incorporated in the simulator. First, the job attribute values are used in determining the routing strategy. In the same class, jobs with different attribute values may choose different routing strategies. If the attribute values can be changed according to some conditions, jobs with the same initial attribute values can have different routing strategies after entering into the network. Second, the service rate at each node is assumed to be constant. It can be modified to give different service rates for different job class. Third, places used in the Petri net refer to the status of the associated link only. Protocol on the link does not interact with other protocols on other links. End-to-end subnet protocol can be simulated by introducing some common places to the Petri net for interaction. Fourth, four groups of accessing strategies, namely, random, probability, priority, and current status are provided. However, other strategies can be easily implemented. For example, since job priority and job size are available in the simulator, exhausted polling or round robin policy can be simulated on multiple queues. Lastly, four types of distributions, namely, random, uniform, exponential and normal are supported. Other distributions (such as Erlang, hyperexponential) can also be easily introduced.

Acknowledgment

The author wishes to thank Chan Chi Kin, Lai Hing Ming and Li Chun Chung for their programming effort in the implementation.

VARIOUS METHODS OF LAN-WAN CONNECTION

Satoru Urata
FUJITSU LIMITED
Tokyo, Japan

This paper introduces various methods of LAN-WAN connections that are often seen in offices and factories. The LAN-WAN connections are analyzed from two aspects: LAN-WAN connecting unit and WAN type. The LAN-WAN connecting units are classified by each function , and their desirable connections are introduced. The application ranges of WAN is evaluated by traffic and speed. In particular, the application ranges by traffic will be analyzed by considering the LAN-WAN traffic characteristics.

1. INTRODUCTION

Companies are adopting LAN in their offices and factories to reduce the number of cables, to install OA servers, and to achieve peer to peer connection. At the initial implementation stage, LAN were mainly introduced into individual offices or factories for closed processing. However, communication between offices and factories has gradually become more important. This has increased the demand for LAN-WAN connections to connect plural LAN within each office or factory. (See Figure 1.)

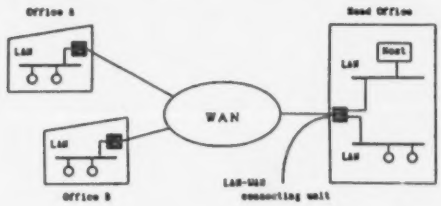

Figure 1 General LAN-WAN connection

There are a great many patterns of LAN-WAN connection. A suitable one must be selected by considering the following two points:

1) LAN-WAN connecting unit
2) WAN type

This paper analyzes LAN-WAN connection from the various points of view by considering actual examples or by using simulation.

2. LAN-WAN CONNECTING UNIT

By taking up actual examples, this section introduces the various LAN-WAN connecting unit types and indicates how to select an optimum one.
They can be classified into two major categories, these dedicated to LAN-WAN connection and those having other functions as well. Each category includes units having different features. Table 1 classifies the LAN-WAN connecting unit.

Table 1 Classification of LAN-WAN connecting unit

Major category	Minor category	Feature
LAN-WAN non-dedicated unit	Controller	Host system connection
	Server	OA server UNIX server
LAN-WAN dedicated unit	Bridge	protocol free
	Router	Preventing MAC broadcast
	Brouter	having both bridge and rou -ter function

3. LAN-WAN NON-DEDICATED CONNECTING UNITS

3.1 Server and Controller

This section introduces the LAN-WAN connecting units that are used for other purposes as well. The first purpose of this unit is for application systems, but it is also able to be used to connect LAN and WAN. This units are thus selected according to the application. The problem is whether the unit can be also used for the LAN-WAN connection.
As this kind of unit which can be used for the LAN-WAN connection, host system controllers, OA servers, and UNIX servers are treated in this section. These units are necessary for the host system connection or for the application, but can also be used as LAN-WAN connecting units.

3.2 Fujitsu Products

Table 2 lists Fujitsu products available as host system controllers, OA servers, and UNIX servers.

Table 2 Fujitsu products available for LAN-WAN connection

Classification	Product name
Dedicated host system controller	NMC
OA server	K series, FMR series, FMG series
UNIX server	A family, S family, DS90-7000 series

3.3 Product Functions and Examples of Use

1) Dedicated host system controller (NMC)

Dedicated host system controllers are used to communicate on behalf of terminals that do not have communications functions. NMC has various interface and is able to connect networks each other. Since the units are intended for host system connections, however, they permit only access to the host system. In a communication system centralized at a single host system, the units cost less than dedicated units such a router and bridge. Figure 2 shows a example of a LAN-WAN connection using NMC. NMC is placed at each office to control the terminals. The terminals and NMC are connected to the same Ethernet. The NMC is also connected to the host computer at the center through leased analog lines. If an office has many terminals, more than one NMC are placed.

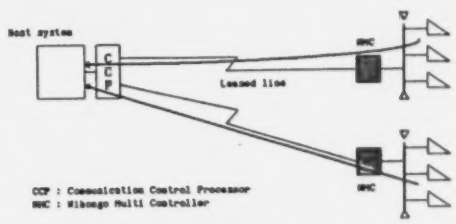

Figure 2 LAN-WAN connection using an NMC

2) OA server (K series, FMR series)

OA servers are efficient in the office as file and mail servers etc. Unlike the host system controllers, they process application programs independently. They must have terminal interfaces but do not always require host system interfaces. To communicate with the host system is additional function.

OA servers which have connection for host are convenient because the user can accessed hosts through them. Since dedicated machines are not necessary, costs are reduced. Figure 3 shows an example of using a Fujitsu FMR as an OA server and LAN-WAN connecting unit. The FMR is worked as an OA server by the LAN Manager software which runs under OS/2. Fujitsu provides a LAN manager for the FMR that also enables connection to Fujitsu's M series host computer. Terminals connected to the Ethernet can thus access the LAN manager on the FMR and also the M series host system through the FMR. This means that the FMR works as a LAN-WAN connecting unit as well.

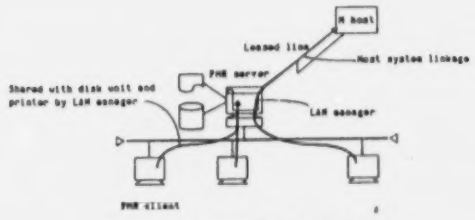

Figure 3 LAN-WAN connection using FMR machines

3) UNIX server

UNIX server may be used for Office Automation, but since the UNIX OS forms a certain field on LAN, the UNIX servers are explained here separately. UNIX machines can function as TCP/IP routers in most cases. So if the TCP/IP protocol is used, a UNIX server can be used as a router. However, it must be noted that application programs on the UNIX server may affect routing performance. The dedicated router and brouter explained in the next section are recommended if the performance becomes degraded or if a protocol other than TCP/IP must be used. In Figure 4, database software is worked on the UNIX server on the Ethernet connected with workstations. On the other hand, a UNIX server is also operated as a TCP/IP router to connect a workstation with a distant workstation on the LAN.

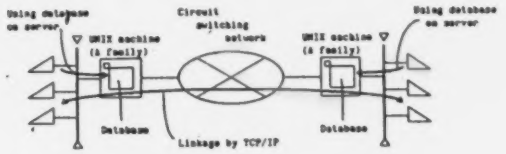

Figure 4 LAN-WAN connection using a UNIX server

4. LAN-WAN DEDICATED CONNECTING UNITS

4.1 Bridge, Router, and Brouter

This section introduces the dedicated LAN-WAN connecting units. The representative dedicated connecting units are bridge, router, and brouter. These units are connected not only for LAN-WAN connection but also for LAN-LAN connection. The units have different features and must be selected according to the conditions. Table 3 lists the advantages and disadvantages of bridges, routers, and brouters.

BEST COPY AVAILABLE

Table 3 Bridge, router, and brouter function comparison

Item	Advantage	Disadvantage
Bridge	protocol free	Unable to block broadcasting packets
Router	Fault range localized by blocking broadcast packets	Available protocols limited
Brouter	Both bridge and router advantages	High cost

The LAN protocols can be classified into ones having layer 3 for routing and those having norouting layers. Following is examples of protocol which have routing layer or not.

- Protocols having routing layers
TCP/IP, OSI, XNS, IPX, DECnet, AppleTalk etc.

- Protocols having no routing layers
FNA, SNA, HNA etc.

Protocols having no routing layers cannot go through a connecting unit or and must be connected by a bridge.
Technically speaking, a router or brouter is desirable for protocols having routing layers. For LAN to LAN connection, however, a bridge is often selected because of easy maintenance or low cost.
For a LAN-WAN connection, router functions are more necessary than for a LAN to LAN connection. If a bridge is used for LAN-WAN connection and a fault occurs, the effect can spread all sites, and a broadcasting packet that cannot be interrupted may flow to WAN.
There are some practical cases that bridges are used to connect internal LAN and routers or brouters are used to connect LAN.

4.2 Fujitsu Products

Table 4 lists Fujitsu bridges and brouters available for LAN-WAN connection.

Table 4 Fujitsu bridges and brouters

Classification	Product name
Bridge	LLU
Brouter	LLU-E

4.3 Product Functions and Example of Use

1) LAN-WAN connection using Fujitsu LLU

Fujitsu supplies LLU as a bridge. Figure 5 shows an example of LAN-WAN connection using the LLU.
In this example, only the host system is connected and the FNA protocol which is not available to router functions is used. So the office LANs are connected by bridges (LLU). Since the LLUs have an FDDI interface, LLU and host system connected each other through FDDI and itcan resolve the traffic congestion at the hostside.

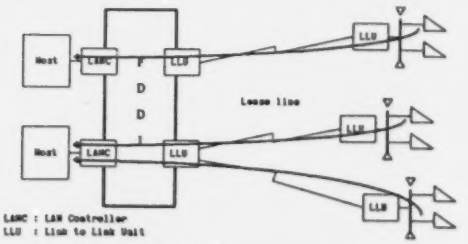

Figure 5 LAN-WAN connection using an LLU

2) LAN-WAN connection using Fujitsu LLU-E

Fujitsu supplies LLU-E as a brouter. Figure 6 shows an example of LAN-WAN connection using the LLU-E. The teminals are connected to the host system or workstation. Two protocols, FNA and TCP/IP are used. The systems use the brouter (LLU-E) which operates as a router for TCP-IP and a bridge for FNA.

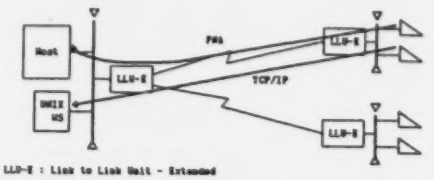

Figure 6 LAN-WAN connection using an LLU-E

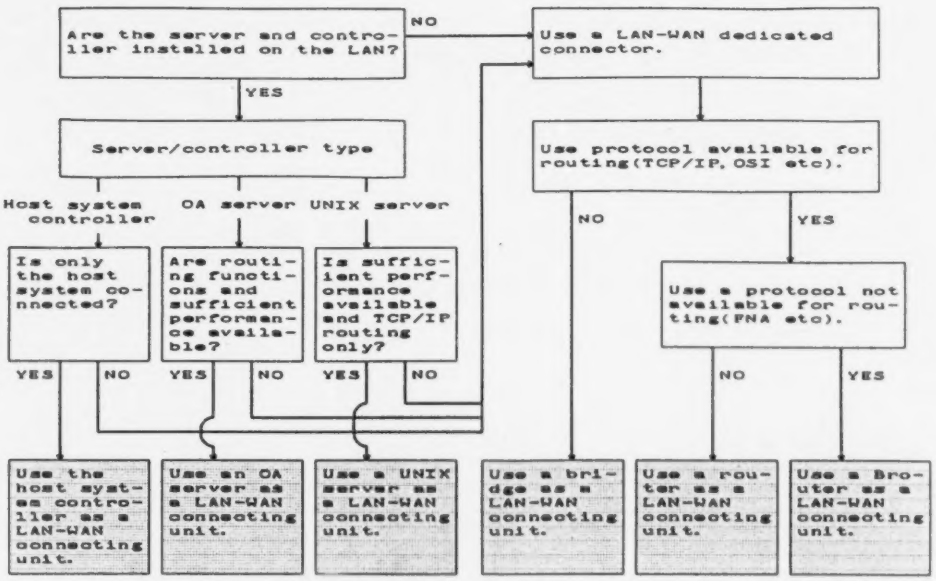
4.4 LAN-WAN Connecting Unit Selection Method

The previous sections introduced the types andsome examples of LAN-WAN non-dedicated and dedicated connecting unit. Figure 7 shows the unit selection guide, explaining the proper selection method of non-dedicated and dedicated units. It is a general guide and may not apply in certain cases, such as the budget is not enough.
In Figure 7, if the path goes to the right after first dropping down through the left side, both server and routers are used. This happens quite often in the practical use. (See Figure 8)



Are the server and controller installed on the LAN?
NO
Use a LAN-WAN dedicated connector.
YES
Server/controller type
Use protocol available for routing(TCP/IP, OSI etc).
Host system controller
OA server
UNIX server
NO
YES
Is only the host system connected?
Are routing functions and sufficient performance available?
Is sufficient performance available and TCP/IP routing only?
Use a protocol not available for routing(PNA etc).
YES
NO
YES
NO
YES
NO
NO
YES
Use the host system controller as a LAN-WAN connecting unit.
Use an OA server as a LAN-WAN connecting unit.
Use a UNIX server as a LAN-WAN connecting unit.
Use a bridge as a LAN-WAN connecting unit.
Use a router as a LAN-WAN connecting unit.
Use a Brouter as a LAN-WAN connecting unit.

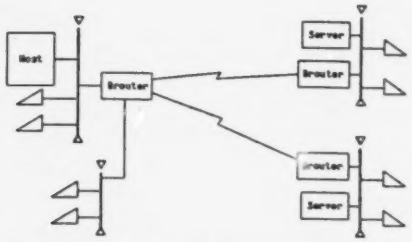

Figure 8 LAN-WAN connection using servers and brouters

5. THE KINDS OF WAN CONNECTING LAN

This section introduces the types of WAN connecting LAN, referring to the WAN application ranges. WAN are classified into following three types, leased line, line switching, and packet switching. They are evaluated in terms of traffic and speed.

5.1 Traffic

Costs is most important factor when selecting WAN. The costs are mainly determined by the distance between two sites and traffic occurence. Here, the relationship between the traffic and network costs is explained.
For LAN-WAN connection, traffic are sent together from a connecting unit. However, since there are several sources, the traffic shows a leveled distribution unlike for point-to-point connection. Considering the traffic tendency, leased lines are generally suitable for WANs connecting LANs.

To show it more concretely, example case between Tokyo and Osaka is used, which indicate relation between the number of terminals on LAN and a suitable network. Figure 9 shows the graph representing the relationship. The more terminals there are the wider the leased line area.

In LAN-WAN connection, the traffic distribution on the LAN varies with the overlapping of traffic from the terminals. Figure 9 shows border between circuit switching and leased line by dotted line in the case of extreme case. The right-hand dotted line shows each terminal traffics completely overlapped. Since the traffic on the WAN is the same as for a single terminal, the circuit switching range is rather wide.

The left-hand dotted line shows border between circuit switching and leased line when the traffic from the terminals is not overlapped at all. This is equal to when the terminals are connected separately to the WAN. In this case , since the time when circuit switching is used cannot be shared, the circuit switching range is small. The solid line indicates the border between the circuit switching and leased line areas set by simulating the actual conditions of use. The simulation almost revealed the same tendency as when the terminal traffic was not overlapped at all.
That is , LAN-WAN connections do not produce the advantage of sharing the time used by circuit switching. In this way, if many terminals share one connecting unit such as LAN-WAN connection, the leased line application range is very large.

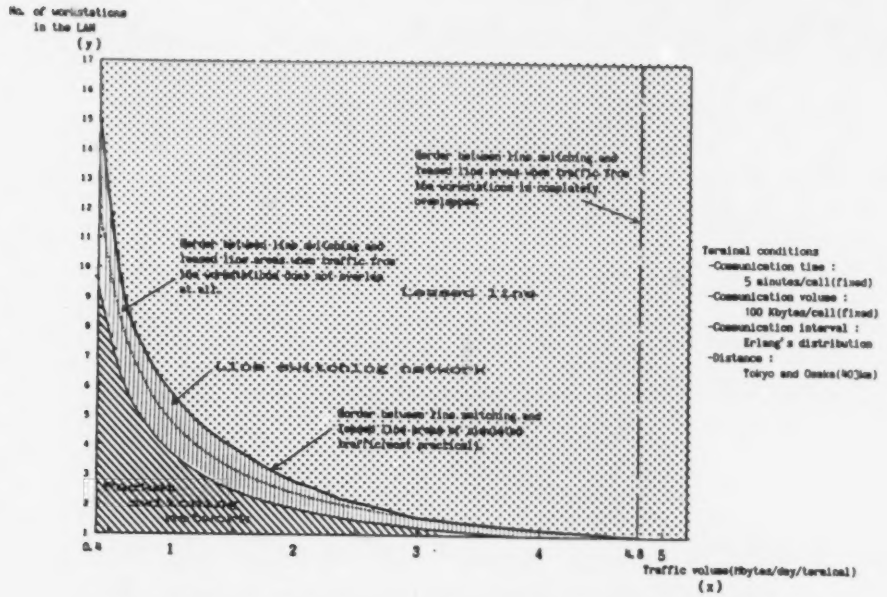

Figure 9 Relationship between the number of workstations in the LAN and the line application range

5.2 Speed

Speed is an important factor in a network , but especially WAN speed in a LAN-WAN connection is more important, because LAN speed is much faster than the WAN speed. Leased line and circuit line can realize the rather high performance , but packet switching is particularly troublesome because of the slow throughput. Especially, if the system must bundle only one character at a time like telnet, packet network is not suitable for LAN-WAN connection because of the low communication efficiency.
Packet switching, however, is superior to other networks in reliability.

5.3 WAN Selection in LAN-WAN Connection

Leased lines are less expensive and have better response for WAN connecting LAN.
But, since the packet switching and line switching have also their advantages, selection should be made according to the conditions.
Table 5 lists the evaluation of WAN in LAN-WAN connection.

Table 5 The evaluation of WAN in LAN-WAN connection

	Circuit switching	Packet switching	Leased line
Response	○	△	○
Cost	△	△	○
Reliability	△	○	△

6. CONCLUSION

This paper discussed various types of LAN-WAN connection from the aspects of LAN-WAN connecting unit and WAN types.
A selection guide and many LAN-WAN connecting examples have been given to help aid in the selection of a connecting unit for actual LAN-WAN connection.
For WAN selection, cost was evaluated by considering the traffic characteristics of LAN-WAN connection. This WANs selection guide is useful when selecting a WAN for a LAN-WAN connection.
It is further subject to consider much faster LAN such as FDDI, FDDI-Ⅱ and much faster WAN such as frame relay etc. It is expected to evaluate these new network in the near future.

SWITCHING OF A REQUEST TOWARDS A DESTINATION ADDRESS ACCORDING TO ITS SEMANTIC CONTENTS

Jean-Jacques MERCIER - Laurence REDON
Equipe de Recherche en Informatique et Communication
IUT 'B'. 5, allées Antonio Machado. 31058 TOULOUSE CEDEX. FRANCE

ABSTRACT

An intelligent network is able to switch a request in a network without knowing first its destination address. We propose to insert a new layer between the transport and the network layers, whose role would be to deduce the destination address of the request according to its parameters and the available services on the network.

INTRODUCTION

Until now in networks, the actors are well-known before the initial set-up of the connection. At the time of the call, the sender provides all the necessary data, and notably the destination address, to reach the remote correspondent. The network layer, as defined in the ISO 7-layers model, knows perfectly the configuration of the physical network.

The semantic transfer networks, also called intelligent networks, constitute a new approach of networks (1). The knowledge of the network's architecture is no longer a constraint. At the time of the interaction, the correspondent is unknown : the network itself must deduce the destination address, that is to say the most appropriate correspondent, according to the semantic contents of the request. So the network appears as a logical entity, which puts a set of resources and services at the user's disposal. This set of resources can evolve dynamically during the session.

The aim of this study is to define a method allowing to locate on the network the working-station to which the request must be sent. A comparison can be done with a cross-domain : such a network's configuration allows users to send their requests without having to know which machine will perform them. However, in a cross-domain, the localization of each application is well-known.

In the first section, we present the context of our study and particularly the integration of the new localization service into the layered OSI model. In the second section, we define the method used to determine a destination address. A bureautic application which implements this function is described in the third section.

I. PRESENTATION OF THE LOCALIZATION SERVICE

I.1. CONTEXT OF THE STUDY

I.1.1. Definitions

In this paper, we define a site as a node to which one or more working-stations are connected. In the following, we consider that every communication between two remote entities is in fact a communication between two working-stations located on two different sites. The figure 1 represents the context of this study.
Each site is addressable by a unique address, and as far as each site is able to deduce the destination address of a request according to its contents, the network can be qualified as an intelligent network.

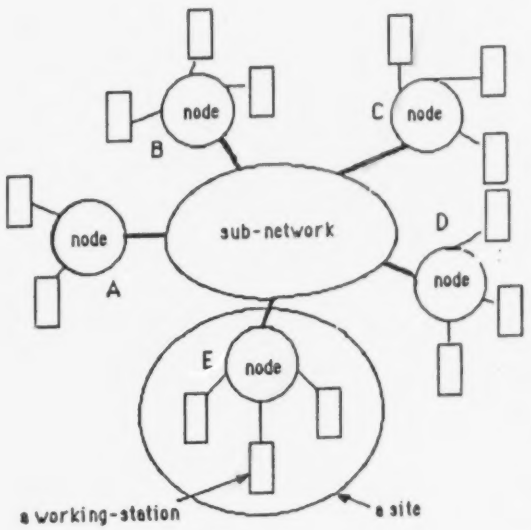

FIG. 1 : SITES LINKED BY A MULTICONNECTION NETWORK

I.1.2. Hypothesis

One of the major objectives for intelligent network is the independence of services towards the network's architecture (2). The proposed localization service is based on the concept of logical network. Therefore the topology of the physical network must not be a constraint or a determining information in the localization algorithm.

In order to facilitate the model of the localization service, at first, we consider that we are in an off-connection mode. The transport service and the network service will use only off-connection primitives as a datagram service.

At last, our aim is to modify the least possible the OSI model while integrating in this layered model a new service : the **localization service**.

1.2. INTEGRATION OF THE LOCALIZATION SERVICE IN THE OSI MODEL

In the proposed model, the user does not have to specify the destination address. So, as the request arrives in the transport layer, the remote correspondent is not still known. In the previous hypothesis (§ 1.1.2), we specified that the lower layers (1 to 3) of the ISO model were not modified. Therefore, a destination address must be provided to the network layer in order to define the routing of the request. That is the subject of our study.
Then it appears necessary to **add a new layer** between the transport and the network layers : the **localization layer** or layer 3' (Fig. 2).

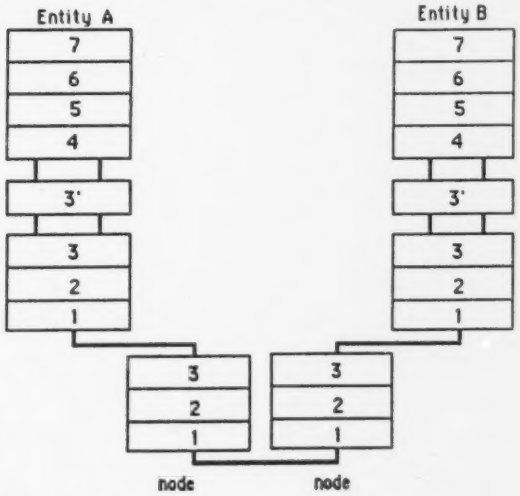

FIG. 2 : THE LOCALIZATION LAYER IN THE OSI MODEL

The localization function forms the subject of a whole layer for two reasons :
- it is wholly independent on one hand of the transport service which ensures the end-to-end connection, and on the other hand it is also independent of the network layer which realizes the routing.
- its function is to provide a service to the transport layer, while relying on the service provided by the network layer. That corresponds to the client-server model of interaction between two adjacent layers of the OSI model (3).

1.3. MODEL OF THE LOCALIZATION SERVICE

The transport layer sends to the localization layer a request without any destination address. So the localization layer defines this destination address with the localization algorithm presented in section II. This address is then transmitted to the network layer which can therefore route the request through the network.

When the destination working-station, which has been considered as the most liable to realize the expected service, receives the request, three cases can appear :
- the working-station can perform the requested service : then it sends a message to the initiator indicating that it will take charge of the request.
- the working-station cannot perform the requested service, a new destination address is chosen and the request is anew directed towards a new working-station.
- the working-station cannot perform the requested service but the request cannot be directed towards a new working-station (no other working-station can perform the expected service; the request is not allowed to travel anew on the network ..). The request's switching is so aborted.

The behaviour of both communicating entities has been represented by a linking of primitives. We propose to associate **L_LOCAL primitives** with the localization layer. The figure 3 shows the linking of the primitives between three sites. The site A is the initiator of the request. As the site B cannot realize the expected service, the request is redirected towards the site C, which will perform the service. So the site C returns to the initiator a primitive indicating that the request will be executed on its site.
The figure 3 gives the linking of the primitives used by the localization layer.
Note : there is no L_LOCAL.ind or L_LOCAL.conf which comes back to the transport layer of the initiator entity because we said that we were in an off-connection context. In this context, the initiator entity is not informed about the path followed by its request or even if the message has been delivered or not to a remote entity.

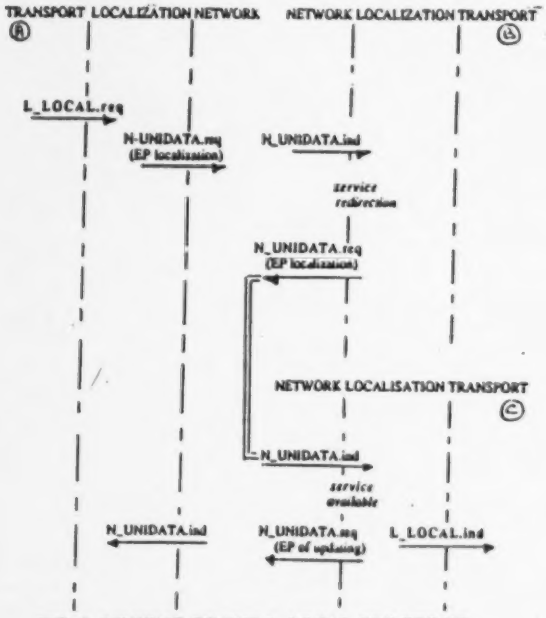

FIG. 3: LINKING OF THE L_LOCAL PRIMITIVES

II. THE LOCALIZATION ALGORITHM

II.1. RECEIPT OF A REQUEST

When a working-station receives a request, it examines its contents (that is to say, it makes the semantic analysis of its contents) in order to know if the requested service can be performed on its local site or not.
- If the service can be performed on the local site, as the request is satisfied, the remote correspondent address is returned to the caller.
- If the service cannot be performed on the site, the working-station checks if the request is allowed to travel anew on the network (every request contains a "chains-counter" : this counter avoids the request to circle indefinitely on the network. Each time the request comes in a working-station, this counter is decremented):
  -- if the "chains-counter" is > 0 : implementation of the localization algorithm and possibly redirection of the request towards another working-station.
  -- if the "chains-counter" is = 0 : abortion of the request's switching.

A working-station (and in the future a node of the network) must be able to calculate a destination address (Fig. 4). It does it according to :
- the contents of the request itself
- the knowledge it owns on the network (it is not knowledge about the network topology seeing that the localization function must be independent of it).

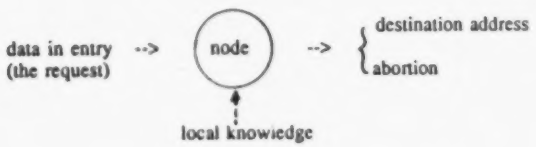

FIG. 4 : DATA USED FOR THE DESTINATION ADRRESS CALCULUS

II.2. THE ADDRESS CALCULUS PARAMETERS

II.2.1. Data in entry

- **the service itself**

- **the type of the expected service** : the available services on the network are gathered in classes according to their function or their domain of use. This classification is necessary for two reasons :
  -- it allows to codify the contents of the request. By this way, the switching of the request is done according to the type of the requested service. The semantic analysis of the request is not necessary to determine the next destination address.
  -- this classification allows also to generate a matrix on the local knowledge of the network (cf II.2.2).

- **the minimum threshold of switching** : the switching of a request is done according to the probability to find the sought-after type of service on one working-station. The user can specify a minimum threshold of switching. So only the working-stations which have a probability to own the requested type of service superior to the specified threshold will be taken in account at the time of the determination of the new destination address.

- **the list of the already reached working-stations** : in order not to come back to a working-station which has already treated the request, the list of these working-stations is added in the parameters of the request. Any new destination address will have to be excluded from this list.

II.2.2. The local knowledge

- **the list of the reachable working-stations** : in order to take in account only the active working-stations at the very instant t of the address determination, the working-station which must redirect the request broadcasts on the network the message 'ES_TU_LA'. The responses of the working-stations which have intercepted this message allow to generate the vector of the reachable working-stations at this very instant.

- **the matrix of the local knowledge** : this matrix CL is (n*m) sized (n: number of listed types; m : maximum number of working-stations connected to the network). Each item CL(i,j) contains the percentage of services of type i available on the working-station j in comparison with the whole number of services of this given type on all the network.

$$CL(i,j) = \frac{\text{nb of services of type i on the station j}}{\text{nb of services of type i on all the network}} * 100$$

II.3. THE DESTINATION ADDRESS CALCULUS

The working-station which must direct the request toward another destination uses the localization algorithm to find, within the reachable working-stations, which one is the most liable to perform the requested service.

Let consider :
- **m** : the maximum number of working-stations connected to the network

- **n** : the number of listed types

- **K** : the type of the requested service (1 < K < n)

- **S** : the minimum threshold of switching (10 < S < 100)

- **SC** : vector of the already reached working-stations. It is a boolean vector.

$$SC_i \quad i = 1..m \quad \begin{cases} 0 & \text{if the working-station has already treated the request} \\ 1 & \text{else} \end{cases}$$

- **SA** : vector of the reachable working-stations at the very instant t. It is a boolean vector.

$$SA_i \quad i = 1..m \quad \begin{cases} 1 & \text{if the working-station is reachable} \\ 0 & \text{else} \end{cases}$$

- **CL** : matrix about the network knowledge (distribution of the different types of services on the network).
$0 < CL_{i,j} < 100 \quad i = 1..n;\ j = 1..m$
The line $CL_{K,j}$ of this matrix is used to calculate the resulting vector.

The result is the vector R calculated as follows :

$$R_j = E\left[\frac{SC_j + SA_j}{2}\right] \circledcirc MIN\left[E\left[\frac{CL_{K,j}}{S}\right], 1\right] \circledcirc CL_{K,j} \qquad j = 1..m$$

The $\circledcirc$ operator is the logical multiplication term by term between two vectors (4).
R is a vector of percentage.

The destination address is so $ADR = i$
as $R_i = Max\ (R_j)$ for $j = 1..m$

Three cases can appear for the value of ADR :
- $ADR = 0$: no working-station can perform the expected service under the specified constraints. So the switching is aborted.
- if many values of R_j are equal to the maximum. That means that more than one working-station can perform the service. In that case, either a choice is made by the user, or new criteria of selection are added and the algorithm is anew executed.
- if there is only one maximum in R, the request will be directed toward this working-station.

The constraints (the list of the reachable working-stations, the list of the not still solicited working-stations), taken into account in this model to determine the destination address, are the minimum constraints. It is possible to add other constraints as :
- the access right to a working-station for a user
- the load of the working-stations in order to balance the load of the machines on all the network (5).

III. THE BUREAUTIC APPLICATION

III.1. CONTEXT : A LOCAL NETWORK

The network which has been used as a model for the implementation of the localization service is a local network, on which eight working-stations of type PC, at the most can be connected. A bus topology has been chosen, while the medium access is done through the CSMA/CD protocol. This bureautic oriented local network allows the user to send requets (as a file transfer or an express message sending) without having to leave its application or to save its work. From the user point, it is a multi-task system on single-task machines (6).

The architecture implemented on each working-station is as follows :

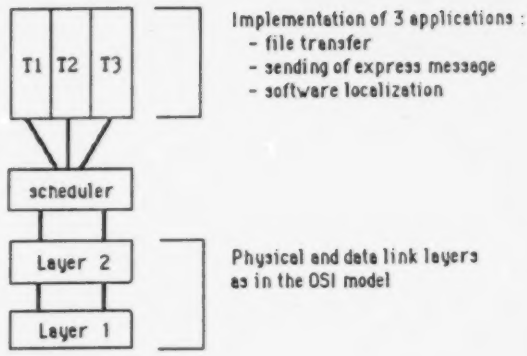

FIG.5: THE LOCALIZATION FUNCTION USED ON A LOCAL NETWORK

III. 2. THE APPLICATION OF SOFTWARE LOCALIZATION

This application uses the localization service in order to locate a software on the network. For example, a user who is looking for the Kermit software questions the network with the request : ' Où_est KERMIT'.
The implementation of this application needs the classification of the software available on the network, according to their function.

III.2.1. The software classification

The localization algorithm presented in section II is based on a local knowledge of the network. In this application, the useful knowledge is the distribution of the software on the network. So as, the software are gathered in ten classes according to their function (fig 6).
This classification allows to generate the matrix of the local knowledge CL. Each item CL(i,j) (i=1..8, j=1..10) gives the percentage of software of type i available on the working-station j, in comparison with the whole set of software of this type on all the network.

FIG. 5 : CLASSIFICATION OF THE AVAILABLE SOFTWARE

III.2.2. Switching of the request

When the request must de directed to another working-station, the research of the new destination address is made in two steps.

• Research of the reachable machines :
The working-station, which must redirect the request, broadcasts the message 'ES_TU_LA' in order to know which working-stations are connected at this very instant. At the same time, a time-out is set, beyond which the working-stations which have not

sent their response will not be taken in account to determine the future destination address.
The connected working-stations which receive the message 'ES_TU_LA' use the file transfer application to return informations about their configuration. In order not to exceed the time-out allowed for the response, the configuration files have priority. The queue of the files to transfer is managed according to this preemptive right.

When the watch-dog is off, the vector of the reachable working-stations can be generated.

* Determining of the destination address
The algorithm presented in section II is then executed to determine the destination address according to the type of the expected service, the global distribution of the software on the network, the list of the reachable machines, and according to the path already followed by the request.

III.3. LIMITS OF THIS MODEL. EVOLUTION TO A LARGER SIZE MODEL

The localization application implemented on this local network store all the data necessary for the localization algorithm and particularly the local knowledge matrix in data files. The use of a distributed database did not seem really useful in this context. Nevertheless on a larger size network, the implementation of a multi-database would facilitate the update of this matrix which is implemented on every working-station (7). The inter-base requests wich are implemented in the multi-database are particularly useful for the update , as far as : *"A n interbase request is an inter-base flow of data contrary to the classical requests which express a flow between the external world and the database. An inter-base request allows to update one or several databases called 'targets' with the data selected from one or several database called 'sources' "* (8).

CONCLUSION

A new approach of networks consists in considering the network as a logical network, that is to say a set of resources and services. In this context, giving the destination address is no more a necessity. The request's switching towards the working-station able to perform the expected service is determined according to its contents. A classification of the different kinds of services available on the network is used in order to have at one's disposal a global knowledge of the network. This knowledge allows to determine which working-station could possibly realize the expected service. The localization function has been implemented on a local network dedicated to bureautic in order to locate a software.

After this first step in our research, we will lead our work in two ways : first it consists in implementing this localization function on a set of interconnected networks (9). In that case, searching for the destination address means, on the one hand finding the network on wich one working-station owns the expected service, and on the other hand, finding in this network the working-station itself. The implementation of the localization on such a configuration would need the use of a database.

The second way of research consists in finding a really intelligent routing based on the semantic contents and not on a codification of it. That means the localization layer should perform a semantic analysis of the request.

SYNCHRONIZING THE EVOLVING NETWORK

ROB AVERY
Telecom Solutions
San Jose, CA. U.S.A.

ABSTRACT

This paper outlines the issues surrounding the present method of master-slave network synchronization, analyzes the impact of the evolving network, and discusses the stability requirements of clock systems to maintain timing performance. Solutions are offered with alternative methods of synchronization operation for the emerging problems associated with timing an evolving network.

1. INTRODUCTION

New technologies are placing an increased demand on telecommunications network synchronization performance. These networks are becoming homogenized to the point where the traditional physical boundary can no longer be readily identified. Mid-span meets of fiber optical facilities utilizing SDH/SONET technologies carry vast amounts of valuable digital information. As the network evolves, SDH/SONET equipment will create digital synchronous islands that require connection to the existing asynchronous network. The originator, intermediate carriers, and terminator of digital information must be synchronized to common, highly-stable, clock sources to ensure complete connectivity and performance objectives.

Achieving precise timing in the telecommunications environment is not a trivial task. Transmitting the timing from node to node has been the inherent problem for all digital networks. Traditional network equipment used to transfer network synchronization, such as digital switching systems, adds impairments to the once-traceable signal. As the synchronization signals are passed from node to node they lose their identity by passing through intervening clocks.

Timing will be an integrated part of all new network deployments. New transmission methods, network topologies and the issues they bring with them necessitate a review of current network synchronization strategies. Challenges that face the network are itemized. Although this paper studies the North American hierarchy, the principles and issues highlighted apply equally to any digital network. It will be demonstrated why distributed primary reference sources in every office and the BITS architecture is a technically and economically viable solution to the issues facing network planners today.

2. BACKGROUND

The evolution of the current digital network has created many timing challenges. The majority of these issues have been solved with hierarchical synchronization and a master-slave timing distribution network. It is necessary to understand the issues that have arisen as a result of the networks growth before the impact of future network strategies can be analyzed. Many of the challenges that were present before will be present again in this evolving network.

2.1 Digital Networks and Synchronization Requirements

In digital networks, all information —whether speech, data, graphics, or video— is coded using discrete, identical pulses. The distinguishing feature of the pulses in a DS1 data stream is their position and relationship to other pulses in time; this allows them to carry meaningful information. All transmitting and receiving network elements (NE) must be kept in precise synchronization to insure that the digital bits are encoded and recovered correctly to accurately represent the information they carry.

Two types of synchronization are required in digital networks. Frequency, or bit, synchronization ensures that the transmitting and receiving equipment operates at the same speed or data rate. Phase, or byte, synchronization establishes the position of a digital word (byte), time slot or frame. DS0 channels (unlike DS1) do not carry framing markers and therefore byte synchronization is provided externally. Both types of synchronization are employed in the network, which allows digital connectivity and facilitates reliable, error-free service.

2.2 Network Timing

Over the years, a synchronization hierarchy has been established with clocks segregated into performance or stratum levels [1]. Timing signals are ultimately traceable to a single clock referred to as the stratum 1 or primary reference source (PRS). The stratum 1 clock, being the highest quality and most stable source, feeds stratum 2 clocks throughout the network and transmits synchronization to other stratum 2 and stratum 3 entities. Similarly, stratum 3 clocks feed other stratum 3s. Stratum 1 responsibility is frequently provided by an interexchange carrier (IXC) —a holdover from the pre-divestiture days in N. America. Stratum 2 clocks are typically located at nodes or access points in a network. Stratum 3 clocks are the least accurate timing sources in the public switched network but are the most commonly used clocks in central offices [2]. Typically, the timing between central offices is conveniently embedded in a message-carrying DS1 facility where the equipment operates in a master-slave mode. Thus, a tree-like architecture is established (Figure 1) with a stratum 1 at the base of the trunk, with stratum 2s at forks of major limbs, and stratum 3 clocks at the extremities.

2.3 Equipment Timing

The Building Integrated Timing Supply (BITS) concept is the preferred method of distributing phase and frequency

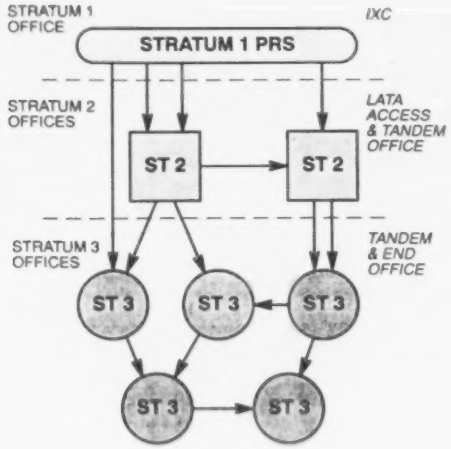

FIGURE 1. Traditional synchronization hierarchy of three performance levels.

synchronization within an office. The BITS clock is usually a stand-alone clock and is referred to as a Timing Signal Generator (TSG) or Digital Clock Distributor (DCD) [3]. For a "true" BITS architecture, the DCD is not a part of any network element (Figure 2). The advantages of a DCD is that its characteristics are designed solely for timing and are not compromised by other functions.

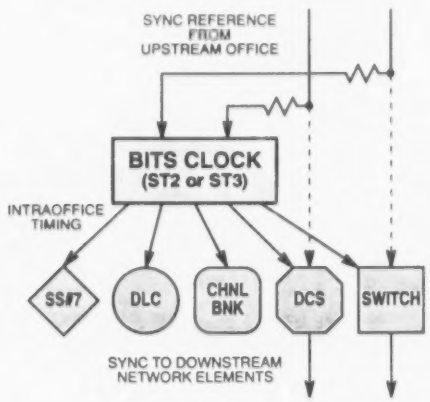

FIGURE 2. Building Integrated Timing Supply (BITS) synchronizes all central office equipment from a single clock system.

The benefits of using the BITS concept are generally found in three areas:

- Increased performance.
- Reduced administration.
- Maximum utilization of resources.

The fact that BITS is location-dependent rather than service-dependent (that is, synchronization is not a function of switching or facilities but a core support service) makes installation and maintenance considerably easier as new digital services are introduced [4]. A BITS also serves to filter a certain amount of perturbations from the timing signal before it's used to synchronize NEs and downstream offices. Ideally, BITS timing should be classified in the same manner as "battery and ground" –it's there when you need it, where you need it.

2.4 New Technology

SONET and SDH is the new digital transport protocol using a synchronous optical network [5,6], promises unrestricted high-quality digital bandwidth from 64 kb/s to over 13 Gb/s, and improvements in "operations, administration, maintenance and provisioning" (OAM&P) functions of the network. Another important aspect is the end-to-end compatibility of terminals. SONET adds powerful access and testing capabilities to a network of terminals and add-drop multiplexers (ADM).

Synchronous mapping schemes are used in SONET which allow individual DS0, DS1 and higher bit rate channels to be "visible" within a SONET signal. This is unlike the asynchronous multiplexing method used today. A 1.544-Mb/s DS1 signal is mapped into a synchronous payload envelope (SPE) within the synchronous transport signal (STS-n) by means of "pointers" (Figure 3) and other additional overhead information. A pointer is used like a "dynamic framing bit" to indicate the start of the SPE or "virtual tributary" (VT-SPE or VT1.5 for a DS1 signal) within the STS-*n* signal. This substantially reduces the transmission delay normally encountered with frame buffers in an asynchronous multiplexer. Because of the synchronous mapping function of SONET, DS1 signals appear to float within the SPE. STS blocks are then combined to form higher rates (STS-*n*) where they are converted to the optical carrier (OC-*n*) on the fiber optic "cable" or light-guide.

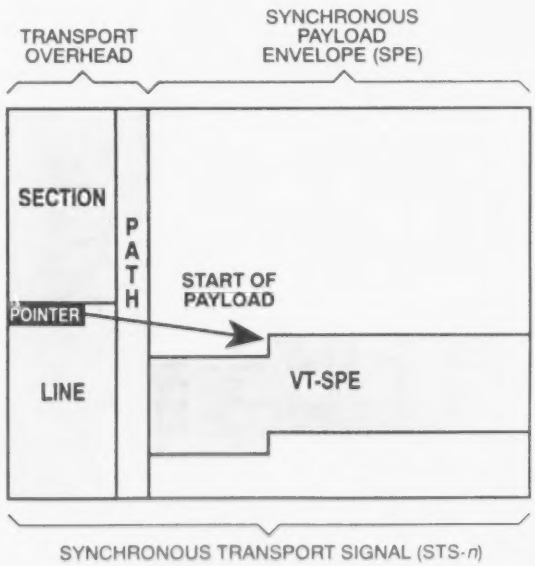

FIGURE 3. The use of pointers to map synchronous payload envelopes within the SONET structure makes DS1 signals float with clock differences.

2.4 *Synchronization Issues*

Current network synchronization issues are basically divided into four categories:

- Intervening clocks add inaccuracies and instabilities.
- Network elements designed for other purposes are employed to distribute timing.
- Specifications for synchronization are evolving and not widely understood by the industry.
- New technologies and topologies create additional problems.

These will be discussed in the following text and presented as a forerunner to the impact of newer networking issues.

Synchronization distribution is linked closely with the structure and topology of the current network where the routing of interoffice feeds are well constrained. However, timing transfer performance of NEs has been, within certain bounds, fairly loose and not (adequately) specified by industry standards below observation periods of 1,800 seconds which is characterized as wander (Figure 4). Frequency jitter, until now, has been the only other synchronization impairment specified in the time domain.

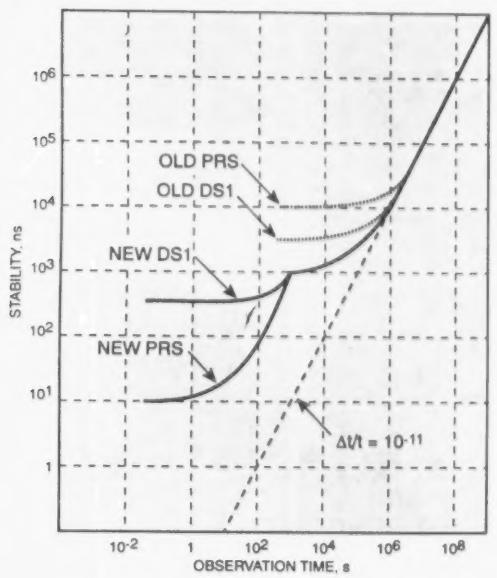

FIGURE 4. Timing stability as defined by T1.101. "New" requirements are contained in the draft revision to this standard (T1X1.3/90-026R6).

As the synchronization reference signal passes from node to node and on to the lowest level in the "food chain", intervening clocks and the transmission medium itself contribute to timing inaccuracy and instability [7]. Long-term variations such as wander are cumulative resulting in poor stability below the 1,800 second range. Although the BITS clock provides timing to the equipment within a central office, it is rare that BITS directly feeds the downstream network. NEs, such as digital cross-connects and digital switching systems, are employed to perform the distribution function (Figure 2). These NEs, as stated earlier, are not specifically designed to transfer timing and therefore add instabilities to the timing signal by the "breathing" effects of their intervening clocks and related system architectures.

To date, the characteristics of the reference as it passes through the network and the resulting impact on network performance are still being analyzed. Many timing issues manifest themselves downstream of the originating problem and are difficult to locate since there are many transients that occur. Upgrades to software and hardware have, and will, introduce additional troubles which are difficult to pinpoint. These troubles will also be present in a SONET based network. Work continues within the T1X1 [8] standards body to provide satisfactory and more detailed specifications for the undefined portion of the synchronization signal (Figure 4). A draft document has been drawn that will supersede the current ANSI T1.101-1987 synchronization interface standard. In this document the short-term stability has been defined. However, the new standards document is not released.

The rush to plug the holes in the synchronization standard is being fueled by the new technology and trial deployment of SONET. SONET, as its name implies, relies heavily on synchronization. Therefore, the stability of its timing source directly reflects its performance. This is also true when SONET is used to transfer timing. The "timing" output of a SONET NE is a function of its input plus any inherent effects from the NE.

Digital NEs (such as DCS and switches etc.) are being offered with integrated SONET transport functions or the promise of upgrades. Most of these existing NEs are currently used to distribute the timing throughout the network. With the introduction of SONET, the entire topology of today's network is being reevaluated. The OAM&P function of SONET will allow the network to be configured for self-healing and automatic reconfiguration by the use of diverse-routing, dual-homing hubs and ring architectures, analogous to "Olympic rings" (Figure 5). While this strategy will potentially aid the long-term integrity of the network, it may actually lower the reliability of synchronization by adding complexity and administrative problems to the timing distribution. No longer will the network be configured in a well constrained hierarchy.

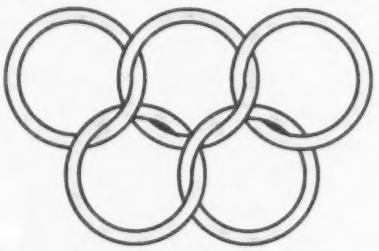

FIGURE 5. As the network evolves. a ring-like structure will be built resembling the "Olympic Rings".

Some network providers have chosen to establish dedicated timing links from node to node via asynchronous NEs which directly connect BITS clocks to BITS clocks at downstream offices. This is, however, a short-term work-around that allows SONET to coexist with the current network by removing

the burden of timing distribution from the SONET transport equipment.

Clearly, the adoption of SONET will have a widespread impact on the current network synchronization distribution plan and place an increased demand on a BITS clock. The increased demand will be a major challenge to insure the transport of synchronization from node-to-node while maintaining stability and traceability to a PRS. The performance of the network (and timing) already suffers from the timing problems introduced by switching and transmission equipment.

3. CHALLENGES IN THE EVOLVING NETWORK

SONET perhaps has the greatest impact on network performance. It potentially brings enhanced digital service offerings and powerful networking capabilities. But with this vast improvement comes a synchronization penalty. The major challenge presented to equipment manufacturers and network planners is how to put the "S" (synchronization) in SONET. Many of these synchronization challenges are common to all digital networks. However, SONET brings several unique issues of its own:

- SONET is a "synchronous" system vs. todays asynchronous network.
- Standards are "understudy" for SONET synchronization.
- VT interfaces with existing NEs and asynchronous networks.
- Existing NEs upgrading to SONET need performance characterization.
- Intelligent networks and rerouting add complexity to the network.
- Added complexity of the network creates administrative issues.
- NEs that distribute timing are intervening clocks.
- SONET adds new requirements on BITS performance and capacity.
- BITS is not widely deployed where SONET will be used.

Synchronization plays an extremely important role in the performance and networking of SONET. Timing variations of DS1 signals entering a SONET terminal will be quantized into 8 unit interval (UI) steps (8 bit periods of a DS1). These appear on the output side of the SONET transport system as 8 UI phase steps created by the mapping function of the pointers (Figure 6). DS3 signals mapped into the STS-*n* will undergo similar phase hits due to timing variations. The rate that the pointer adjustments (8 UI phase steps) occur per day will depend on the relative clock offset of each SONET terminal in the network. Recent studies [9] have shown that the mean time between pointers (MTBP) could be as little as 13 seconds. The resulting effect of these pointer created-phase steps has still to be evaluated in a functioning networked SONET.

Any time a DS1 (intended to distribute timing) is passed through a SONET NE, it will be subject to the phase steps caused by pointer adjustments. The 8 UI pointer justification on DS1s amounts to approximately 2.8 microseconds phase change and may be a significant impairment. DS1s embedded in DS3s before passing through a SONET transport system will also have the 8 UI phase step. But since the DS3 isrunning at a much higher bit rate, an 8 UI transient at 45 Mb/s will be in the order of 160 nanoseconds (or 1/4 of a bit at DS1) and will not greatly affect the embedded DS1's performance. However, once a DS1 or DS3 is mapped into a SONET transport system, it is difficult to control its routing through an integrated network of cross-connects and add-drop multiplexers. Because of the potential for rerouting, it is impossible to differentiate a DS1 suitable for network timing from one that is not.

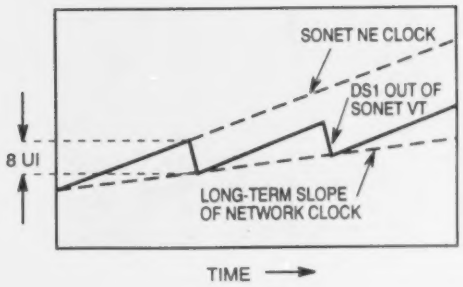

FIGURE 6. DS1 output of SONET VT1.5 signals will have periodic 8 UI phase steps or pointer adjustments.

One potential solution recommended by Bellcore [10] is to provide a method of using the optical line rate (OC-*n*) of SONET as a synchronization medium. To allow the evolution of SONET based timing distribution, NEs in central office applications should provide the capability to time the BITS by providing a DS1 reference derived from the ON-*n* carrier (Figure 7). Each SONET NE will use "timing only" ports (DS1s) from the collocated BITS to time its internal clock and clock the OC-*n* carrier. The receiving SONET NE will then directly convert the OC-*n* line rate to a pair of timing DS1 ports to be used by the local BITS as the reference signal.

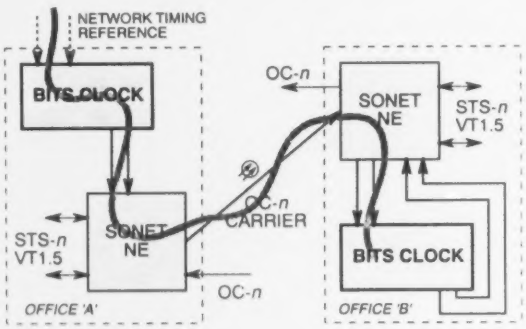

FIGURE 7. Timing distribution via OC-n carrier of a SONET transport system, BITS-to-BITS.

OC-*n* based timing is offered due to its immunity to facility rearrangements. It is not subjected to the phase steps resulting from pointer justification and has transparency from source to sink. However, this is a very simplistic view of transporting synchronization via SONET and does not address the complex network topologies in which SONET will be used.

3.1 SONET Network Complexities

In a network environment, when timing is carried via the OC-*n*, each SONET NE will regenerate the OC-*n* signal under control of the NE internal clock and pass that signal to

downstream NEs. Therefore, timing characteristics can be expected to accumulate toward a maximum allowable limit as the timing is passed from office to office. The internal clocks of some NEs in service today (which are planned to be upgraded to SONET transport systems) exhibit excessive short-term timing instabilities and/or do not meet the current stratum clock specifications. Using OC-*n* timing will require each NE to be evaluated on a case-by-case basis before including it in the timing plan. SONET ADMs will also use internal (intervening) clocks to regenerate timing and pass it to the next, downstream, ADM. The internal clock must, therefore, meet the new stringent (understudy) short-term stability requirements.

The adoption of a survivable network by the use of SONET rings, route diversity and automatic reconfiguration places an additional requirement on the SONET NE and BITS clock. Intelligence must be provided that determines the derivation of the timing source, whether it is suitable as a reference, and whether or not a choice should be made to search for other possible timing sources (other OC-*n* links, diverse network feeds or holdover). Selection and administration of reconfigured paths —suitable for timing references— becomes very complex. This scenario is commonly classified as *the network from hell*. Each network configuration and the various failure modes associated with it require analyzing and proof of performance certification before each new link and additional NE can be placed in service. This network model grows geometrically as links are added.

Synchronization messaging plays a key role in smart networks. As listed above, the NE must be able to identify viable timing links (Figure 8). A proposal is currently being discussed within the T1 standards bodies [11] that will assign a synchronization message or identity to the ESF data link of a T1 and allow this information to be mapped onto the SONET overhead structure. Generically the synchronization message will contain the source of timing and the status of the intermediate clock. This new standard is a formidable task since it requires all equipment vendors and network providers to work in consort to ratify the requirement. Until such time as a standard is worked out, each SONET vendor will utilize proprietary schemes to enable SONET networks to operate in all configurations. It will be difficult to dislodge a working method once a standard is issued.

Each SONET NE (and other new NEs) require a pair of DS1 timing-only feeds. These are to be provided by the BITS with a high-stability clock. Many large central offices have existing BITS architectures. However, in many cases BITS has not found its way into the smaller end offices; instead, they remain "loop timed". SONET and other new services will push the need for high-quality BITS at all offices due to the demand for a large number of stable timing sources. This is particularly true in the end-office environment where SONET based local feeder NEs are being deployed (Figure 9). These SONET "local" terminals will be expected to interconnect with switched digital services and other asynchronous transport systems.

Clock requirements for SONET are known to be extremely stringent. SONET vendors have expressed a need for signals with very tight short-term timing characteristics. The source for these signals will be via the BITS clock. Currently, the industry standards bodies (T1X1.3/.6) are actively negotiating applicable limits. These limits will be based on the effects

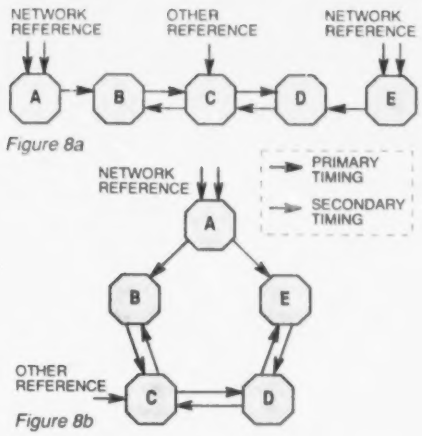

FIGURE 8. Synchronization messaging is required in this configuration so that each NE is capable of finding a valid reference. The linear network (8a) is considered as having identical issues as the ring (8b).

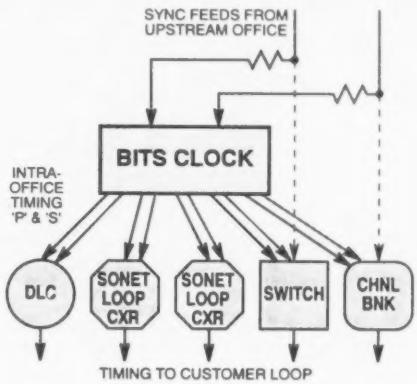

FIGURE 9. Additional BITS capacity will be requirements to time end-office SONET based local distribution.

of empirical data applied to a "SONET reference model". The BITS is therefore considered as a SONET timing filter. It will provide the very precise stability required by the NE to minimize pointer justification and assure the performance of the SONET-based network (Figure 10). Most stratum 2 based BITS clocks will meet the requirements proposed however tight the stability mask becomes, but the specifications must be known before any judgment is made on existing stratum 3 BITS clock compliance.

3.2 The Same Old Argument

SONET has now brought the network planner and synchronization coordinator full circle. The original arguments for adopting BITS in the mid 1980's has many of the same issues that SONET deployment brings today:

- Multiple timing feeds/choices.
- Network administration.
- Strain on office timing (BITS) performance and capacity.
- Effects of VTs on "end users".

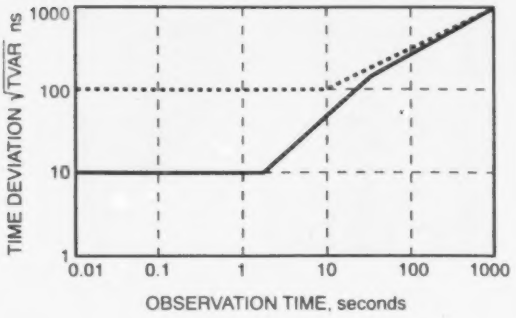

FIGURE 10. Short-term timing stability requirements for SONET. 10ns stability is required for NEs without timing filtering. 100ns stability is considered as the maximum allowable input.

Primarily, BITS reduced the number of timing feeds entering a building and provided a known clock source for uses throughout the central office. These two factors alone effectively eliminated the administration and operations burden that was in place before BITS. Now, due to SONET and other changes in network transport, the issues are confronting the network operator once more. In addition, the reference to the BITS may not be as constrained as in the past due to network reconfiguration capabilities of SONET and DCS-type architectures.

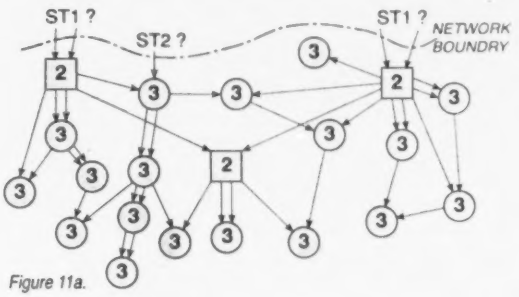
One solution to the network puzzle is not to rely on SONET for interoffice synchronization but to continue to use the existing asynchronous facilities. This strategy mandates that two independent networks are maintained. This may not be practical since most telephone companies are phasing in SONET-based transport systems that will "optically isolate" offices by replacing existing facilities.

One of the first uses for SONET-based transmission is in the local feeder area. Private networks which currently derive timing from a DS1 feed via the local LEC will have no control of the timing source and routing of these signals. Once the local network migrates to SONET, the potential of phase hits caused by the VT pointers may have an adverse effect on performance of the customer's network, and its ability to interconnect with other networks. The full impact of VT pointers on the customers synchronization is not known.

Smart networks are not limited to SONET architectures. 3/3 and 3/1 digital cross-connects can also provide the dynamic network reconfiguration, rings and route diversity that SONET offers. One problem that does arise in a total electronic office —where the manual DSX-1 has been replaced by the a DCS— is the fact that there is no physical access to a DS1 signal where the BITS clock extracts timing from the upstream node. This may be the case as existing offices are converted to "all digital" in an effort to reduce maintenance and operations.

4. DISTRIBUTED TIMING

The technologies available in the mid 1980s allowed the widespread, economical, adoption of BITS. However, this (existing synchronization plan) still relies upon the transport of timing from office to office and master-slave operation with its attendant problems. An alternative to transporting timing from the single PRS location to the far extremes of a network is to deploy distributed PRS clocks in every central office (Figure 11). Each site can be coordinated with UTC (UTC–universal coordinated time on the international time scale as maintained by the Bureau of International Weights and Measures, Paris, France) and operate plesiochronously with other PRS sites in the network much the same way interexchange carriers (IXC) do today.



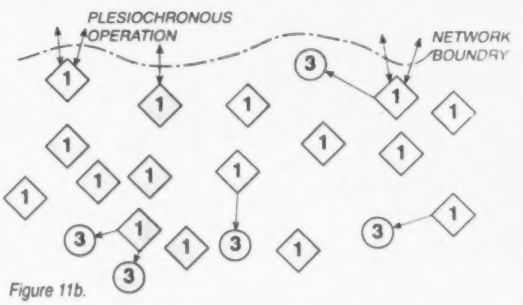


FIGURE 11. Distributed PRS sites remove the timing distribution network, administration and maintenance requirements. Links between networks will now operate plesiochronously.

The recent modernization of LORAN-C (a low-frequency radio-based navigation aid that covers most parts of the Northern Hemisphere) by the US Department of Transportation (DOT) and the initial deployment of Global Positioning System (GPS) satellites by the US Department of Defence (DOD) allows the recovery of a stratum 1 signal from the LORAN or GPS transmitter's cesium atomic clock ensemble by using low-cost radio receivers [12]. Both LORAN-C and GPS PRS BITS clocks can provide long-term stabilities in the range of parts in 10^{-12} (an equivalent slip rate measured in years), and short-term stabilities in nanoseconds, which is well within the requirement for a stratum 1 source and proposed SONET standards. The DOT and US Coast Guard has funding in place to maintain the LORAN-C system for civil users through the year 2010. A continuing modernization plan is underway that is upgrading each LORAN transmitter to fully automate the operation and coordination within 100 nanoseconds of UTC [13]. It is uncertain what policies cover the GPS system since it is military based and maintained by the DOD.

Distributed PRS or PRS in every office effectively eliminates the issues and problems encountered when timing is transported via SONET or via the asynchronous network. In this configuration, all NEs have access to the highly stable synchronization source that is now required (Figure 12). The payback from removing the need for interoffice synchronization administration and operation easily justifies the small initial expense of the distributed PRS clock equipment.

FIGURE 12. Loran-C transmitters are located throughout N. America and other Northern Hemisphere areas providing continuous 24 hour coverage.

4.1 Benefits of Distributed PRS

Several significant advantages are gained by embracing a distributed PRS architecture/BITS clock:

- The distributed PRS strategy is autonomous of network architecture and rearrangements and removes the requirement for timing distribution maintenance and administration.
- The network operation and performance is not compromised by slaving to an unknown source of an adjacent network.
- Distributed PRS insures quality timing, independent of the introduction and deployment of new technologies and topologies.
- Synchronization messaging is not required since there is no timing distribution.
- The BITS clock is engineered specifically for the best timing reference acquisition, generation and transfer qualities.
- BITS clocks can be upgraded or modified at any time without impacting major network elements.
- BITS clocks are free of design compromises and availability common in other NE clocks.
- Little or no timing network transport is required which mitigates intervening clocks in the timing chain. Only the BITS provides timing.
- Synchronization performance is enhanced due to the removal of timing distribution which generally is the main contributor to timing impairments.
- Cost of embedded clocks in NEs can be reduced since they are not required to transfer or distribute timing.

Clearly these factors cannot be ignored when analyzing the distributed PRS strategy. Moreover, by removing the transport element from timing distribution, the instabilities introduced by the facility transport elements are minimized to a point where they may not be a factor for SONET timing.

5. VERIFICATION

Since each node operates autonomously and interoffice links are now plesiochronous, a method of synchronization verification must be implemented. A synchronization monitor system (SMS) [14] derives a reference from the local PRS and uses this to compare outgoing and incoming facilities from other PRS nodes and networks (Figure 13). Performance limits assigned to each monitored point enable the user to verify synchronization performance remotely and take appropriate action before service problems occur. The benefits for the network operator of network-wide synchronization surveillance are:

- Survey adjacent PRS nodes and downstream office performance.
- Verify and compare incoming timing feeds.
- Compare timing from other networks and customers.
- Examine individual network element clocks.
- Monitor the timing distribution to remote offices and within the office.

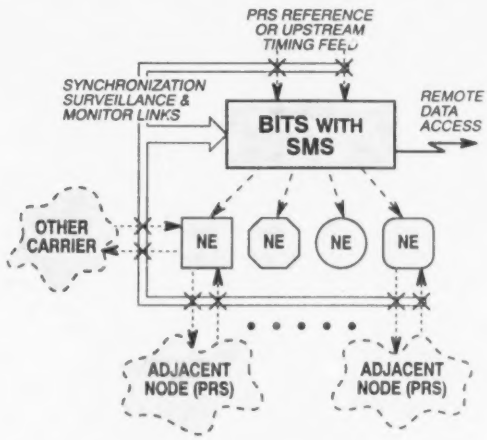

FIGURE 13. Synchronization Monitor System (SMS) verifies and assures the timing of the network.

Over time, a "picture" of the characteristics for each generic NE can be built. Through discriminating software, the network operator can classify and identify troubled equipment and network problems before they become performance or service issues.

6. SUMMARY

The implementation of BITS was a clear winner in the late 1980s. However, the network's ability to transfer timing effectively has remained as the roadblock to an ideal synchronization plan. SONET and SDH will exacerbate the already taxed office clocks by placing increased capacity and performance demands upon them. The robustness that SONET can provide to synchronization networking by using its optical carrier and self-healing/alternative routing schemes does, in fact, add complexity to the timing distribution.

The challenges of today's (and tomorrow's) network can be met technically and economically by the new approach of distributing the primary reference source function to every central office via LORAN-C. This removes the distribution issues entirely and ensures that all network elements receive precisely the same timing – all the time.

Verifying timing through a synchronization monitor system will play an increasingly important role. This coupled with a distributed architecture will facilitate a proactive maintenance philosophy and assure the synchronization control necessary for any new transport technology.

Distributed PRS will provide a new level of superior synchronization that has widespread benefits for all digital services and network performance in general. The distributed PRS/BITS architecture will provide the extremely stable timing required by SONET and SDH at its source without the issues of transporting timing throughout the network. This will provide the platform for future technologies and topologies to migrate into the network of tomorrow, today.

Architecture for a Large-scale Digital Mobile Communications Network

Mitsuaki Hanaoka , Akihisa Nakajima and Fumio Kondo
NTT Mobile communications Sector
Tokyo,Japan

1. ABSTRACT

The architecture for constructing a new large-scale mobile communications network is described. This network is developed to meet the explosive increase in demand for mobile communications. Requirements for this network are also described, in particular, that it must be constructed at low cost and must be flexible and sophisticated enough to provide many inexpensive services for customers.

2. INTRODUCTION

In recent years, demand for mobile communications has increased significantly in many countries. In Japan, demand for portable telephones and car-mounted telephones is also growing by more than 50% a year. To meet future demand, it will be necessary to expand capacity, and improve flexibility and economy of mobile communications networks. On the other hand, the development of ISDN in fixed networks demands diversified and sophisticated requirements for mobile communications services. To satisfy these requirements and future demand, digital mobile communications networks are being constructed in numerous coutries.
This paper proposes the following items for large-scale mobile communications network architecture based on digital mobile technology NTT is currently developing.

1. A pursuit transit switching function to reduce large-scale network costs.
2. A multi-unit mobile-switch configuration in high density areas of mobile stations (MS).
3. Call control architecture with end-to-end signalling transfer capability to make mobile call control easier.
4. A concept of intelligent digital mobile communications network to enhance networ services.

3. BASIC CONFIGURATION OF THE MOBILE COMMUNICATIONS NETWORK

Generally a mobile communications network, where mobile stations move freely, has three logical functional mobile communications control centers to provide automatic roaming and automatic pursuit routing [1] .The basic configuration of a mobile communications network is shown in Fig. 1.

1. G-MCC - is the gateway switching center nearest the fixed network. It has a gateway function from the fixed network and a pursuit routing function using location information.
2. H-MCC - is the network data base center that stores information such as the location of mobile stations and subscriber class.
3. V-MCC - is the switching center where mobile terminals are practically roaming. It can connect call to radio equipment such as base stations (BS) and mobile stations.

At NTT, those three logical centers are connected by the CCS No.7 network and calls are controlled through it.

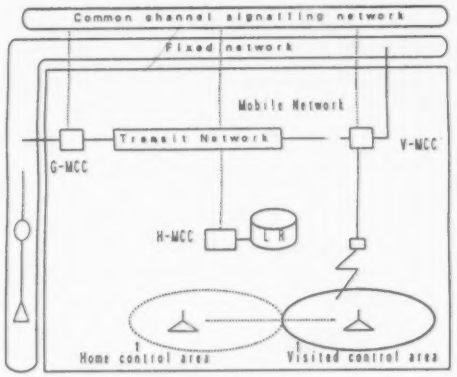

Fig.1 Basic Configuration of a Digital Mobile Communications Network

4. PURSUIT TRANSIT SWITCHING FUNCTION

In a mobile communications network with automatic pursuit routing, inter-office trunk lines between G-MCCs and to V-MCCs are needed to make calls. Also, inter-office trunk lines between V-MCCs are needed to perform handovers. If the network is small, as in the initial stage of a network, trunk lines between MCCs can be offered as a mesh. However, the larger the network, the more expensive the truck lines. As a result, transit switching for pursuit routing is necessary for efficient use of trunk lines between MCCs [1] .

In metropolitan areas where MCCs handle the large demand, each MCC has both G- and V-MCC functions. However, as shown in Fig. 2, it is inefficient to connect trunk lines from a fixed network to all MCCs. The network should instead be made physically hierarchical by concentrating the G-MCC function into some MCCs, as shown in Fig. 3. Comparing the non-concentrated (mesh) case with the concentrated one shown in Fig. 4, it is clear that the latter one is more economical than the former one. However, by introducing the concentrated G-MCC, it is necessary to incorporate the transit switching function (T) which transfers calls to target MCCs

in the mobile communications network. From the viewpoint of MCC capability, the T function should be combined with the G function and physically implemented in G-MCC. The G and T function in G-MCC is called pursuit transit switching function. Thus, to achieve a large-scale economical mobile communications network, a two-stage one [a gateway and transit stage (possessing G-MCC) and a subscriber stage(V-MCC)]is recommended, as shown in Fig. 5.

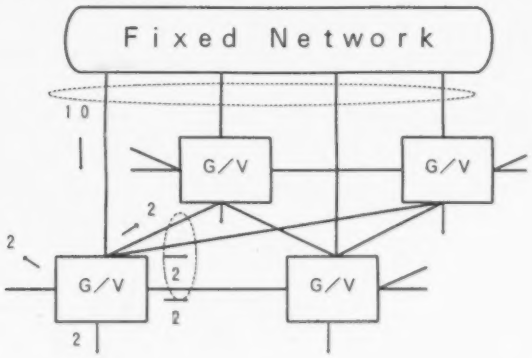

Fig. 2 Prime Mobile Network Configuration

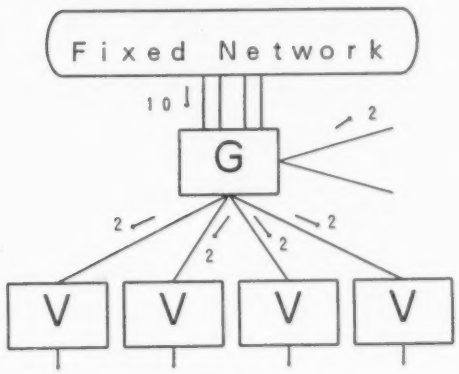

Fig. 3 Concentration of the G-MMC Function

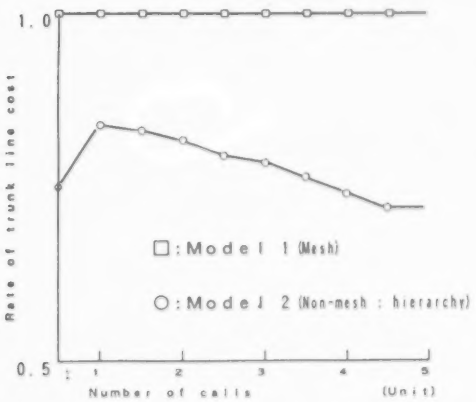

Fig. 4 Estimate of Trunk Line Cost

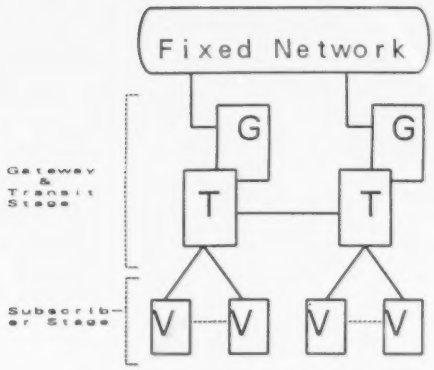

Fig. 5 Two-staged Mobile Network Configuration

In this mobile network, to guarantee personal mobility and terminal mobility, Personal Telecommunications Number (PTN) and Mobile Station Identity (MSI) must not correspond to any network resources such as MCC and location area. It must be a logical number independent of the network. Since the transit switching function can not route calls using dial information as in a fixed network, it is necessary to define the specified Pursuit Routing Number (PRN), for use only in the network, to physically identify each MCC. PRN usage is shown in Fig. 6. G-MCC can get MSI from PTN and it can also get location information for the mobile station and PRN of V-MCC. The transit network then routes the call to the V-MCC using the PRN.

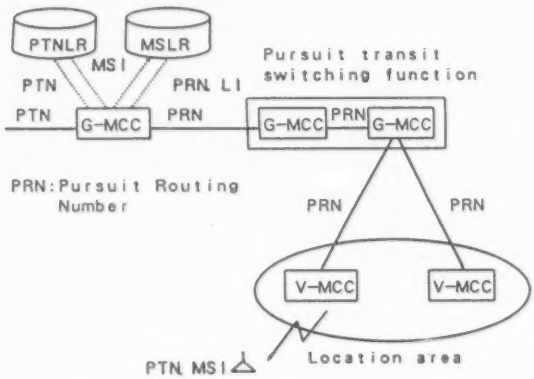

Fig. 6 Pursuit Transit Routing

5. MULTI-SWITCH SIMULTANEOUS PAGING (MSSP)

In the current mobile communications network, every radio zone is equipped with the mobile radio base station (MBS) and one location area has several radio zones, as shown in Fig. 7. The geographical position of the mobile station is identified by the location area. When the mobile station moves to another location area, it is necessary to update the location information in the H-MCC. A location area is synonymous with a paging area where mobile stations are simultaneously paged by the MCC when a call is made to a mobile station.

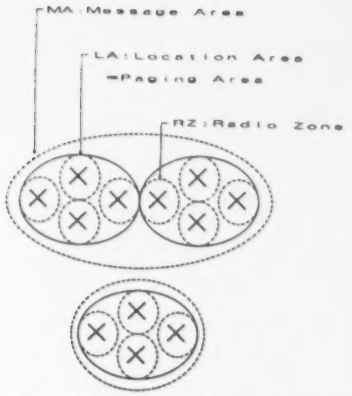

Fig. 7 Area Configuration of Mobile Communications Network

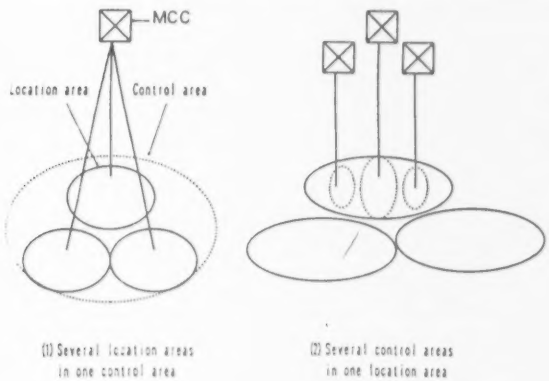
In the former network, a control area had several location areas, as shown in Fig. 9-(1). The number of location registration signals and paging signals varies depending on the size of the location area. In general, as location areas becomes smaller, the number of location registration signals increases because mobile stations cross location areas more frequently. On the other hand, the number of paging signals decreases because the number of MBSs sending paging signals decreases. Therefore, the most suitable size of a location area is determined independently of the number of mobile subscribers, as shown in Fig. 9. As described above, in the prime network which has a small number of mobile stations, a control area has one or several location areas. The control area can be large, as shown in Fig. 8-(1), but in a large-scale network where MS density is high due to increased demand, the control areas are smaller. If a location area has a number of control areas, as shown in Fig. 8-(2), the multi-switch simultaneous paging (MSSP) method[9] is necessary, as shown in Fig. 10 . In this configuration, several MCCs page the mobile station at the same time.

The following is an outline of MSSP. When the G-MCC receives a call at the mobile station, it routes the call to the V-MCC using the location information obtained from the H-MCC. Then, a random V-MCC routing method is applied in which the V-MCC connected to the G-MCC is randomly selected by the G-MCC. This method is most desirable because



MCC
Location area
Control area

(2) Several control areas in one location area

Fig. 8 Location Area and Control Area

mobile stations in control areas, except the control area of a failed V-MCC, can be paged even if a V-MCC system fails. As for setting up the trunk line between the V-MCCs, first, the trunk line between the G-MCC and V-MCC is set up. Next, the V-MCC sends a paging signal to other V-MCCs using a non-related circuit common channel signal and all V-MCCs page the target mobile station. The trunk line between the V-MCCs is complete once the mobile station answer signal is received.

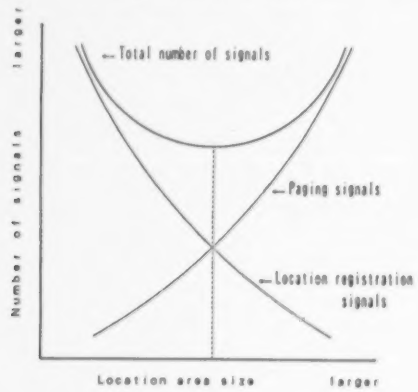

Fig. 9 Relationship between Area and Number of Control Signals

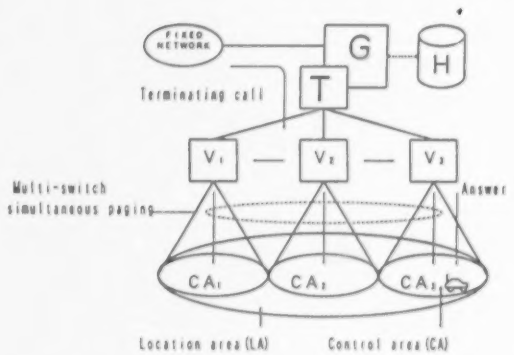

Fig. 10 Multi-Switch Simultaneous Paging

6. CALL CONTROL ARCHITECTURE WITH END-TO-END SIGNALLING TRANSFER CAPABILITY (CC-STC)

In mobile communications networks, the call control function is generally executed by V-MCC, which connects a traffic channel to a target MS. Therefore, when the MS roams from the source MCC to the destination MCC, as in inter-office handover, the call control function is transferred to the destination MCC, which then becomes the V-MCC.
As it will be necessary to expand mobile networks in the very near future, the following obstacles will be encountered.

1. Physical resources (e.g., call waiting trunk) to support supplementary services are fixed at the source MCC in basic handover. After handover, therefore, the destination MCC requires functions to control these resources.

2 If there are subsequent inter-office handovers, the trunk lines between the source MCC and the destination MCC, shown in Fig.11, is established each time. This makes trunk lines utilization ineffective.

3 If the call control function is transferred to the destination MCC in handover, data implicitly indicating the routing address to the call control MCC needs to be updated in a H-MCC. This is because a second call to the MSS must be routed to the destination MCC. If the second call is terminated before updating, the call is routed to the source MCC and cannot be processed.

To resolve these problems, call control architecture with end-to end signalling transfer capability (CC-STC) is proposed[4].
V-MCC functions can be divided into service control, handover control and radio channel interface. Independent of the target MSS's position, service control and handover control are fixed in one MCC, called an anchor MCC. During a call, the physical resources to support supplementary services are controlled only by the anchor MCC, which is the source MCC in basic handover, making it easy to control the resources. Trunk line use becomes efficient because lines are established between the anchor MCC and the destination MCC at every handover (Fig. 12). Furthermore, the call control function can be fixed to the anchor MCC, to route the second call to the anchor MCC (i.e. the source MCC in basic handover). This makes it unnecessary to update the data in a H-MCC.

To adopt this call control function, the V-MCC establishing the radio channel needs to transfer call control signals on the subscriber line from a mobile station or a mobile base station (MBS) to the anchor MCC. In this transferring of signals, the MSS or the MBS is one end point and the anchor MCC is the other. This method is therefore called call control architecture with end-to-end signalling transfer capability. The CC-STC can effectively control calls to offering advanced services similar to ISDN services.

7. INTELLIGENT DIGITAL MOBILE NETWORK (IDMN) ARCHITECTURE

As demand for mobile communications expands, the mobile communications network must be enhanced to offer services that customers really desire. Intelligent Digital Mobile Network (IDMN)[5] corresponding to Intelligent Network (IN) modeling is one way to enhance present mobile network.

The latest study defines the Intelligent Network (IN) model as a hierarchical configuration from the viewpoint of service control. It consists of the following levels:

1 Service Management Point (SMP)
SMP is a logical node in the upper part of the intelligent layer characterized by various functions such as service definition.

2 Service Control Point (SCP)
SCP is a logical node in the lower part of the intelligent layer. It directly controls the

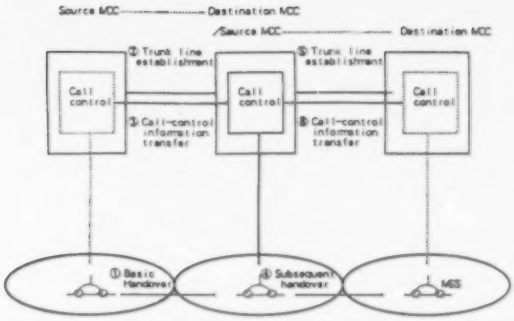

Fig.11 Call Control Transfer for Handover

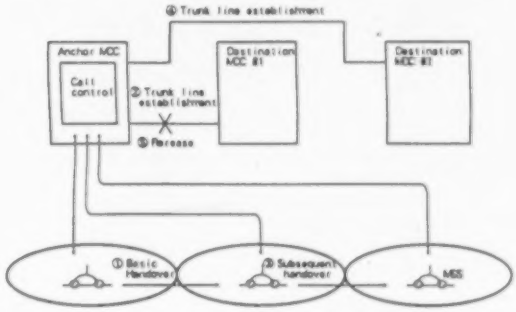

Fig.12 Transit Circuit Establishment in Handover with CC-STC

transport layer.

3 Service Switching Point (SSP)
SSP is a logical node in the transport layer. It provides the actual services.

When this model is applied to a mobile communications network, H-MCC (or Home Location Register (HLR)) corresponds to SCP because it guarantees mobility and also because it is a service control database directly controlling MCCs. Furthermore, because provision of customer-defined services in a mobile communications network will be mandatory, a logical node corresponding to SMP will be needed to enhance services. The intelligent layer should therefore be further divided into two sublayers.

The transport layer is defined as SSP in the IN hierarchical model from the viewpoint of control. G-MCC and V-MCC correspond to SSP. However, this layer should be divided into sublayers because it includes many call connection control functions in the mobile communications network.
G-MCC is located at the call originator side and it includes pursuit routing and call transit functions.
V-MCC mainly controls the base stations side Moreover, since these two logical nodes are located at different physical locations in terms of the call they should be defined as different sublayers. Furthermore, the radio frequency transmission control function, which is allocated to BSs, should be defined as another sublayer because it mainly depends on the radio transmission scheme.

A hierarchical IDMN architecture based on the above concept is shown in Fig. 13. From the viewpoint of service control, the intelligent layer consists of service management and network control sublayers. From the viewpoint of call connection control, the transport layer consists of pursuit routing, call control, and radio frequency control sublayers. The current mobile network should be enhanced according to this index from now on.

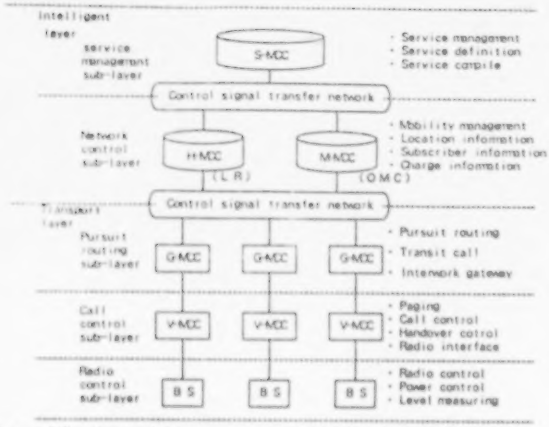

Fig. 13 Intelligent Mobile Communications Network Architecture

8. CONCLUSION

This paper described the architecture for a large-scale digital mobile communications network. Pursuit transit switching function, multi-switch simultaneous paging and call control architecture with end-to-end signaling transfer capability were specifically proposed, and the index for constructing an intelligent digital mobile communications network was also shown.

NTT is now developing digital mobile communications systems, applying the above architecture to construct a large-scale mobile communications network. The system will start gateway/transit-stage services in 1992 and subscriber-stage services in 1993.

RURAL TELECOMUNICATION SERVICES IN MALAYSIA

Dr. A.R. Tharek
Radio Communication Research Laboratory
Faculty of Electrical Engineering
Universiti Teknologi Malaysia
Kuala Lumpur, Malaysia

1. Abstract

Providing telecommunication services to rural areas, can facilitate many development activities including agriculture, industry, education, health, etc. Therefore, the planning of the telecommunication system for these remote areas is critically important. Malaysia has developed a good telecommunication infrastructure which can be extended to rural areas making telephone services possible to great many remote areas.

1. Introduction

It is quite clear from last decades that economic development of a nation goes hand in hand with development of communication resources. The importance of telecommunications in the economic development of the country and its relationship to increase productivity, efficiency and enhancement of the quality of life is well known. Both developing and developed countries require as many telecommunications tools as possible to deal with the diverse and difficult conditions they must face in bringing service to rural and remotes areas. By providing telecommunication services to rural areas, can facilitate many development activities including agriculture, industry, education, health, etc. Rural areas not linked to the telecommunications network are unable to fully participate in social and economic development programmes. The socio-economic benefits to be gained from the introduction of rural telecommunications are increased local employment, reduced transport cost, marketing will be more efficient, emergency services will be more readily available and reduced the sense of isolation.

2. Requirements For Rural Telecommunication Systems

In planning future telecommunication networks, consideration should first be given to the development of rural areas as an essential part of a harmonized evolution in a given country. Rural telecommunication planners should consider the latest technological advances and evaluate the possibility of their introduction in this part of the network.[1]

The rural network development in Malaysia started in 1957 with the introduction of two programmes namely Rural Payphones and Rural Automatic Exchanges. The rural payphones are public payphones installed under the "Rural Public Telephone Programme" started since 1959. Till 1987, a total of 6031 rural payphones had been approved costing Government an estimated sum of M$51.2 millions. The estimated cost of providing a rural telephone is M$15,000 per service in comparison to only M$3,000 in urban areas while maintenance is about 8 times that of its urban counterpart. All the rural payphones are strategically located so that they are readily accessable by the publics. However the exchanges in rural areas were mainly manual and the standard distribution plant was of aerial construction.

In Malaysia agricultural production continues to contribute a decreasing share of the economic output but provide employment for a large proportion of the population. Morever, the Malaysia's Industrial Master Plan has focused on resource-based industrialisation. However, agriculture is imposed with a main problem i.e. the low price of its products, most of which is sold in raw form. Information and knowledge have emerged as the critical strategic factors for growth, increased value-added and competativeness in the modern economic environment. Therefore by providing telecommunication services to rural areas will have significant long-term influence in lifting the agricultural sector from its present low quality, low productivity and low cost status. Telecommunications can improve efficiency and productivity by making price information available to farmers and helping in the timely delivery of products. It can also attract industry and allowing the decentralization of economic activities away from major cities. Furthermore, the creation of natural resources project in remote region can necessitate the urgent installation of few communication facilities.

Studies have demonstrated that rural telecommunication services play an important role interm of improving the socio-economic of a country such as:

(a) increasing the efficient use of existing infratructure to alleviate transport bottlenecks in the delivery of imports to agriculture, and promoting energy conversation;

(b) improving the operation of the market mechanism by extending access to information, encouraging more efficient marketing of agricultural products;

(c) improving the efficiency of government administration, including the coverage of advice and supervision by scarce middle and higher level technical and management personnel and reducing administrative bottlenecks and unneccesary travel;

(d) improving the delivery of healthcare and emergency services such as ambulance etc.

The normal evolution of telecommunication services start with major cities and highways linking them. The challenge facing is to provide the rural telecommunication services. However, there are several factors which pose immense obstacles to the development of telecommunication services in rural areas. To overcome the rural problems, we must understand the rural environment and take into account its characteristic. First is the distance where conventional cable transmission systems for long distance would be very expensive. Terrain and hostile topographical obstacles add futher difficulty where mountains, rivers, swamps and forest pose major problems for the development of telecommunication services. The climate is another potential problem. Heavy tropical rainfall and high humidity affects equipment and attenuates microwave signals. Electrical power supplies can be non-existent in rural areas. Due to the result of all these factors the cost of providing good telecommunication services to these network may low to begin with. However, good telecommunication services can themselves stimulate industrial and commercial growth.

There are a number of system options available for developing rural telecommunications wireline, single- channel radio, multiple access radio and cellular radio. These can be described as follows:

(a) Copper cables are being used to provide services to customers within the immediatel vicinity of up to 20km from the telephone exchange.

(b) Single channel system can provide a service to an individual customer located up to about 40km from a suitable entry point to the national network. This distance may be extended to about 80km if a repeater is used.

(c) Small capacity radio system, both existing analogue and digital, can provide links from the existing national network for variety of purposes. These include link to remotely sited telephone exchanges at small settelements or to provide dedicated circuits to high calling rate customers.

(d) Digital multiple access radio system become increasingly more usefull in more thinly populate,

inaccesible locations. Such a system is able to provide service to customers located up to 600km from a suitable entry point to the national network.

However, using the cellular network to penetrate these remote rural locations is probably the fastest way of reaching new subscribers. It can be as an integrated resource not just for mobile users, but also for widespread rural subscribers. Therefore a cellular mobile telephone network is a tremendous starting point for rural network development.

3. Cellular Radio Network in Malaysia

The world standard for cellular systems are currently operating in the frequency bands around 450MHz, 800MHz and 900MHz. The lower frequencies have better propogation properties, so they would be best suited to rural applications. Therefore cellular system operating at 450MHz is the most suitable frequency for rural network development with lower traffic capacity. However 800MHz and 900MHz are becoming the most common frequencies for cellular networks in urban areas. Furthermore, frequencies around 1.7GHz will be used for future Personal Communication networks (PCN).

The global growth of cellular telephony has turned it into a mass-market industry. Competitive pressures mean that technical developments will continue, and prices will continue to fall. This will make cellular techniques even more suitable for rural network development.

In Malaysia we have already got the cellular network infrastructure in place, so any new ways we can use it to represent only a marginal additional cost. In rural areas it is less costly to provide a cellular telephone than to lay special transmission line. Although Malaysia's industrialization is proceeding rapidly, especially in Kelang Valley area between Kuala Lumpur, the national capital, and the peninsula's west coast, the majority of the nation's land mass is still tropical forest land. The percentage of the population living in urban areas has indeed risen from 27% in 1970 to 34% in 1980, but many Malaysia's villages are in comparatively isolated areas many miles from the nearest town..Therefore the cellular system will provide basic telephone communications to many isolated areas where service using conventional distribution plant is expensive.

First Malaysia's cellular mobile telephone system is called ATUR, an acronym which stands for Automatic Telephone Using Radio It is based on Nordic Mobile system with (Radio Base Station) RBS and exchanges provided by Ericsson. The first phase of the ATUR system was put into service in January 1985 thereby establising Malaysia as the 13th country in the world having mobile cellular system. At the end of 1985 Malaysia became the first country in Asia with a fully automatic nationwide cellular mobile telephone system[1]. The use of 400MHz for the first phase of the system has provided almost natiowide coverage to 329,749 square kilometre country by only 86 RBS, most of which have a coverage area of about 30km. The highest station in the whole system is on Mt. Kinabalu in Sabah, 2231 meters above sea level. There also are stations in Malaysia on Kedah Peak at 1217 meter and Gunong Ulu Kali at 1772 meter. These high altitude stations serve larger areas than at lower sites.

For this system the country is divided into five service areas, each serve by one mobile exchange as shown in fig. 2. The mobile exchange are at Kuala lumpur, Penang, Johor, Sabah and Sarawak. Each of these areas acts as the home area for a mobile subscriber, and all calls addressed to such subscribers are directed first to the home exchange and then to the mobile. ATUR is specified according to the Nordic Mobile Telephone system standard NMT 450 using 180 channels with 26kHz separation in the frequency range 452 - 466.5 MHz.

A 900MHz cellular telephone system was put into services in 1988 to complement the ATUR 450 service. The service areas are mainly in major cities and towns in Malaysia. and is specified according to the TACS standard. Since ATUR system provide natiowide coverage which cover rural and remote areas therefore it is more suitable for providing rural telecommunication services.

One important thing that need to be considered is the cost of

BEST COPY AVAILABLE

purchasing a cellular telephone. The price of cellular phone today is beyound the means of most people, especially the Asean countries. In rural areas we are talking about those poor farmers who earn just enough to buy the basic necessities of life. Having put up a cellular telephone telephone system for rural areas we cannot ask them to buy their own individual cellular telephones. The practical thing to do is to provide a phone that everybody can use but without imposing on them high cost of the cellular telephone i.e. a public phone which can be connected to the cellular system. Therefore we can plan for fixed cellular phones as the basis of rural telecommunication network.

4. Public Telephones

Malaysia poineers the concept of using the mobile telephone system to provide telephone service to rural areas via Coin Collecting Box (CCB) public telephones. A special radio interface unit was developed by Ericsson for Malaysia which makes it possible to connect the standard CCB telephone to the ATUR network and thereby eliminate the physical wire connection as shown in figure 3. Call fees from CCB telepnone are same as those from ordinary cable-fed pay phones, so there will be a substantial measure of cross- subsidization. Malaysia's poineering effort in this area has received world-wide recognition and we are very honoured that other developing countries are looking at "Malaysian Model" as a complementrary solution to their rural telecommunications needs.

Approximately 500 coinbox telephones in all states of Malaysia are in operation so far, under the control of Telekom Malaysia. The distance from the coinbox telephone to the radio unit can be up to 2 km. This gives the possibility of installing the antenna on a hill or on a nearby high building. Power comes from the main supply or from solar powered baterries. The transceiver is connected to a high gain YAGI antenna, so that the unit can be placed even further away from the Radio Base Station site. By using Yagi antenna at RBS the effective range can be increased. The coverage in rural areas can be further increased by using higher power at RBS with a consequent increase in effective range. Besides being used to provide the rural telecommunication services, fixed installations are also being used in urban areas in order to provide temporary network due to shortage of local cable and wire line exchange capacity.[3]

5. Satellite Systems for Rural Communications

If the areas with extended range cannot be reach, we can turn to satellite techniques and microwave point to point links which can be used in the cellular network strategy. Satellite transmission links between the mobile switching centre and RBS allows RBS to be installed virtually anywhere.

Furthermore, the use of satellite based solutions to overcome the technical and economic difficulties associated with expanding the public telephone network into the rural areas has been a subject of great interest. The outstanding advantage of satellite systems lies in the nature of their coverage, which also permits the establishment of a nation wide network.

6. Conclusion

In general rural telecommunications cannot produce sufficient revenue to recover capital and operational costs. As a result, a large gap can generally be seen in the number of telephones being installed in rural areas as compared with urban areas. Telephones in developing countries mainly concentrated in the major cities, leaving the majority of the popupation without access to the service. However, by making used of the existing cellular network infrastucture this problem could be overcome. The cellular network can play an important role in developing rural communications and lets rural communities benefit from a new communications resource that originally created for the business sector. The well-to-do users of mobile users can be happy in the knowledge that they are , in effect, making affordable telephone service possible to great many remote areas.

Papua New Guinea Telecommunication Network Development

N C Mobiha
Papua New Guinea University of Technology
Lae, Papua New Guinea

1. ABSTRACT

Papua New Guinea (PNG) is large in size and population compared with other Pacific Island nations. With an economy based largely on mineral exports, telecommunication development in PNG has, over the years, centred on providing services to meet the mining industry's needs as well as other business organisations in urban PNG. In so doing, it has fulfilled the national government's objective to generate revenue in order to sustain growth and development. However, the second objective of extending services to most citizens remains to be fulfilled.

2. THE COUNTRY

Papua New Guinea (PNG) with a population of 3,529,539[1] and land area of 462,840 square kilometers is the largest of the developing nations in the South Pacific. The country comprises the mainland with 85% of total area and some 600 islands in the Bismarck and Solomon seas.

In the 1990 census, 85% of the national population were shown to live in rural[1] areas of PNG, and rely heavily on subsistence farming for their existence. The rural population growth rate is 1.7% with the urban 3.17% and national at 2.03% per annum.

PNG has 20 provinces with population figures given in table 1. Population density varies from 3 persons per square kilometre in coastal areas to 20 in the highlands region. The five highlands provinces; Chimbu, Enga, Eastern, Western and Southern Highlands have 37% of the total population.

No.	*Province Name*	*Capital*	*Population*
1	Western	Daru	108,705
2	Gulf	Kerema	68,060
3	Central	Port Moresby	104,584
4	National Capital Dist	Port Moresby	193,242
5	Milne Bay	Alotau	157,288
6	Northern	Popondetta	96,762
7	South Highlands	Mendi	302,724
8	Enga	Wabag	238,357
9	Western Highlands	Mt Hagen	291,090
10	Chimbu	Kundiawa	183,801
11	Eastern Highlands	Goroka	299,619
12	Morobe	Lae	363,535
13	Madang	Madang	270,299
14	East Sepik	Wewak	248,308
15	West Sepik	Vanimo	135,185
16	Manus	Lorengau	32,830
17	New Ireland	Kavieng	87,194
18	East New Britain	Rabaul	184,408
19	West New Britain	Kimbe	127,547
20	North Solomons	Arawa	*

*North Solomons census could not be taken due to political crisis during the 1990 census.

Table 1. Provinces, capitals and populations.

1 Rural population is defined as areas with a maximum of 500 and density of less than 195 persons per square kilometer and no urban services, e.g. water, electricity etc.

Rugged mountain terrains cover most of PNG, the remaining areas are swampy plains with very little flat land. Provision of telecommunications services to people in different parts of the country can be a very difficult task: not only must it be reliable and efficient, but it must also be economically sound.

The PNG economy is based mainly on agriculture, forestry and mineral exports. Foreign aid also helps supplement the national budget - Australian aid, which is the major source of foreign aid, has been decreasing at 5% per annum since 1986.

In 1988 coffee generated 9% of total exports while agriculture/forestry as a whole generated 28%. This left PNG excessively dependent on minerals. The closure of Bougainville copper mine in May 1989 and unfavourable mineral prices on the world market saw the growth in Gross Domestic Product (GDP), which had been 4.5% per annum from 1985 to 1988, drop to 3% in 1989 and is expected to decline further in 1990[2].

Increases in mining and exploration activities will result in corresponding increases in telecommunications needs: a very important requirement of mining industries. These needs are usually new radio links and terminals or increases in system capacity - exchanges capacities, radio bearers and so forth.

International traffic measured in paid minutes using Both Way Traffic (BWT) has increased on average by about 5% per annum since 1982. Most of the increases would be due to mining related activities. Table 2 gives some idea on the volume of international traffic (in paid minutes) between PNG and countries in other regions of the world. It is worth noting that traffic between PNG and South Pacific nations also show increases.

INMARSAT stations are a new development in the network. Since 1987, 4 stations have been installed and made operational, normally serving as standby or backup for part/total failure of the terrestrial networks. Over the years, failures have been due to human error, equipment malfunction - lightning strikes, flat batteries and individual component failure, or as is often the case, vandalism by landowners[2] demanding land compensation payments.

2 In PNG land is traditionally owned by the people.

Table 2. Both Way Traffic in Paid Minutes

2.1. Telecommunications

The national government's objectives in telecommunications are principally two-fold. First, that a good affordable quality of service be made available to as many people as possible and second, that the service be financially self supporting to continue improving the service for the people of PNG.

Entrusted with the task of fulfilling the government's objective is the Postal and Telecommunications Corporation (PTC). It has a workforce of just under 3000, 6% of which are non-citizens. This portion is likely to be maintained over the next five years, to provide training for national staff and expertise required for the operation and maintenance of the latest equipment in digital radio and satellite technology in the proposed network developments.

PTC was the only statutory organisation in PNG to return at least 16%[3] return on investment in 1990.

Annually since 1988, over 100 million Kina (K1 ≈ USD 1.03) in total revenue is generated by the Telecommunications Division of PTC. This amounts to 88% of total revenue for the Corporation. 67% of the deposition of revenue would be in operating overheads, labour and maintenance of mostly telecommunications related projects in urban areas.

3. PNG TELEPHONE NETWORK: AN OVERVIEW

3.1. Exchange Hierarchy

PNG telephone exchange hierarchy[4] has five levels[3]. The highest, level 1, is the international gateway exchange in Lae that provides switching for international traffic. Level 2 or the national transit exchange also in Lae caters for the switching of domestic traffic between two primary or level 3 exchanges. Seven primary exchanges make up level 3 and perform two functions: provides switching for a subscriber in direct local service areas of the primary - a level 4 function or acts as local transit exchanges for switching of traffic between any remote small local or level 5 exchanges. Level 4 exchanges comprise only 2 main local or stand alone exchanges. These have direct routes to exchanges of levels 1 to 4 and provide terminations of telephone lines in their service area. The lowest level, level 5, consists of 43 small local exchanges that provide terminations of telephone lines in their local service areas and are parented to a primary exchange. Level 5 exchanges can route calls to/from their own subscribers but calls to/from outside call area must be switched through higher order exchanges.

3.2. Radio Bearer

The difficult mountain terrain between major PNG towns makes communications possible only by use of radio. Frequencies in HF, VHF, UHF and SHF bands are used for different traffic requirements.

HF frequencies are used for low grade service rural outstation radios owned either by government or private organisations[5]. HF subscribers operate into manual assistance centres for access to the national network.

VHF/UHF band caters for small to medium[6] capacity systems with high grade of service offered to subscribers usually within coverage area of a primary exchange or repeaters with drop/insert facilities.

UHF/SHF or microwave bearers are large capacity and carry the bulk of network traffic, standard radio bearers between centres are of 960 channel capacity.

Given the geography of PNG, it is often necessary to use repeaters on mountain tops, at 1000 to 4000 metres accessible only by helicopter, to provide communications. With different manufactured equipment, operations of the radio bearer are either at 2 or 6 GHz. Some repeaters on the national network bearer have facilities for drop/insert of spur routes with some 300 channels capacity.

In 1988 a major network development was the replacement of radio bearer equipment on the main bearer linking Boroko, Lae, Goroka and Mt Hagen. The new equipment supplied by NEC provides two 960 channel telephone bearers (operating on a 1:1 redundancy), one spare 960 channel telephone bearer and a TV bearer which provides live TV transmission to the three centres from studios in Port Moresby. The NEC equipment, can be converted to a digital bearer with minor modifications.

Solar power is used in all repeater sites with battery banks having capacities designed to provide reliable supply in low sunlight conditions for durations of up to a week. Remote monitoring of repeater stations status conditions is possible using sub baseband (SBB) frequencies on the NEC equipped radio bearer.

The last of the bearers are the two troposcatter links, one from Madang to Lombrum, Manus province and the other from Cupola, Gulf province to Daru, Western province. It is possible to link Daru by microwave. Manus however is beyond line of sight distance, it will not be possible to replace this link with a microwave bearer.

3 PNG government return on investment required is 16-22% per annum.
4 Exchange statistics excludes North Solomons Provinces

5 In 1987 there were 1919 HF outstations, only 390 were government owned.
6 Small capacity have 20 or less channels, medium greater than 20 less than 120 and large capacity greater than 120 channels.

3.3. Telex Network

The current Electronic Telex Exchange (ELTEX) in Lae was installed in the seventies. It is driven by a PDP11 computer utilising Stored Programme Control (SPC). With the introduction of facsimile there has been a decrease in the number of telex subscribers and equipment annually. Subscribers from Port Moresby are linked to the ELTEX by a line concentrator at the Boroko exchange.

Telex utilises Voice Frequency Telegraph (VFT), Speech plus Data (S+Dx) and TDM to 'stack' telex channels on a single voice channel. Statistics to date show TDM channels to be increasing at the expense of VFT/S+Dx channels.

3.4. International Network

PNG is linked to the world firstly by a cable, APNG and secondly a INTELSAT B type earth station located at Port Moresby. Both of these were commissioned in 1985.

The APNG cable is from Port Moresby to Australia and has a capacity of 4 supergroups (SG) only 3 are used. The extra SG is for additional traffic from the earth station should there be a failure. International traffic for the cable is switched and designated (in the 960 channel or 16 SG bearer) from the AXE 103 exchange, in Lae. The cable has a design life of 15 years and it is anticipated that by then low capacity fibre optic technology would be available to replace APNG.

In June 1990 APNG circuits total 199: 186 voice, 1 non voice and 12 leased circuits. Only six countries had direct circuits to them with Australia having a total of 165.

Traffic to the Earth Station is also designated and switched from Lae. Voice activated Single Channel Per Carrier (SCPC) and Companded FDM (CFDM) techniques are employed on the space link to countries around the world. In June 1990, there were a total of 88 satellite circuits (46 SCPC, 42 CFDM) comprising 83 voice and 5 non voice to 13 countries around the world. Australia had 24 satellite circuits allocated.

With the AXE 103 digital exchange, International Direct Dial (IDD) is now available to nearly all subscribers in PNG. Apart from it's general switching role, the AXE 103 computer also performs management and house keeping functions resulting in vast improvement to the overall performance and efficiency of the national telecommunications network.

4. DEVELOPMENT PLANS

4.1. International Network

Scientific Atlanta has been awarded a contract to upgrade the current B class earth station to INTELSAT A. Intermediate Data Rate (IDR) will be introduced initially to Australia and thereafter to other countries with or intending to use IDR.

Two SG of the APNG cable will be digitised by 1992. At the end of it's design life (year 2001), APNG is likely to be replaced by an optical fibre cable.

Another international digital gateway exchange is planned for Port Moresby to ease congestion on the Port Moresby-Lae bearer and provide services not available from the analogue exchanges. Currently international traffic originating or terminating in Port Moresby goes to Lae first and then back to Port Moresby occupying twice the bearer capacity required if directly switched from Port Moresby.

4.2. Domestic Network

4.2.1. Domestic Satellite (DOMSAT)

Increasing land compensation demands and outage times on major bearers, due often to damage to repeaters, has caused inconvenience to subscribers and decreased revenue collection. This has forced PNG through PTC to proceed into satellite technology earlier than anticipated.

Scientific Atlanta, has again been contracted to build 13 fixed earth stations, in major towns around the country and 4 transportable mobile stations. A transponder from PALAPA B-2P satellite at 113°E will be used with the earth stations to provide a thin route telephony service, a number of 2MB/s digital carriers and a TV channel. The DOMSAT Hub station will be in Port Moresby.

The PALAPA lease will be for 3 years after that PACSTAR an Asian Pacific Regional Satellite System will provide the service. PNG has 20% share in PACSTAR.

Overall performance requirement of the 3 services: telephony, 2MB/s digital bearers and TV, will be governed by the INTELSAT Earth Station standards (IESS).

Initially, an interim DOMSAT scheme is planned to provide five earth stations, four of which would be used in mining towns and one by the government.

4.2.2. Other Planned Domestic Developments

All analogue exchanges and microwave radio bearers are scheduled to be replaced with digital ones. The main bearer between Port Moresby and Lae will be commissioned first.

Fibre optic cables will replace metropolitan junction cables in Port Moresby and then Lae.

PNG Packet Switch Network (PANGPAC) operates between Lae and Port Moresby. Growth in number of subscribers with increasing demands for use by centres other than the above two will see this service expand nationwide.

A data link using the INTELSAT BUSINESS SYSTEMS (IBS) satellite is to be installed in Lae.

4.2.3. Costs

Overall, the expected investment (in millions of Kina) for the planned developments are:

DOMSAT	13.5
INTERIM DOMSAT	2.9
DIGITAL UPGRADE	2.95
IBS	0.146

5. ACKNOWLEDGEMENTS

The author should like to acknowledge the help of K.Laeka, P.Loko of the PTC Engineering Division for information concerning the proposed developments, and Professor G.H.Bryant and the PNG University of Technology for making this paper possible.

Satellite "Cellular" Telecommunications User, my Experiences and Problems In a Mobile Society Improves the Pacific Hemis[illegible] Cultural Growth and Development

Dr. Angel A. Navarro and Ms. Marcelo Z. Navarro
Gabun-Paracale Mining Co., Inc.
NASA-NCR, Philippines, Inc.
Manila, Philippines

1. ABSTRACT

Many Satellite "Cellular" Telecommunications users adheres to modern amenities benefits such as ISDN applications and the new concept "IRIDIUM" for the emergent behavioural needs in case of disasters/accidents and public safety is concerned. Also, the main concern of the Pacific Rim Telecommunity here is network Interconnecting by intermodal networking and local networking. The Satellite "Telenetworking" by cellular mobile systems has improved not only cultural growth and development in urban and remote areas it will definitely bridge technical, economic, political, social/cultural and spatial gaps in this 14th Pacific Telecommunications Conference.

For the Regional Interests and Global Issues as well as the Challenges of Telecommunications[1] Integrations for the Pacific.

2. Satellite "Cellular" Telecommunications[2] users.

2.1 Our real experiences and Technical Problems to Resolve on the Pacific Rim Telecommunity.

Satellite "Cellular" Telecommunications users will bring real benefits and generalized for the Large Area networking in the uses of the ISDN application for the Integrated Services Digital Networking. This will also improve the "Spectrum" management from the Pacific Rim Telecommunity for the Global networking in different countries. This has also improve the program management for ISDN applications users in Integrative networking, if we use the unified solution in regulatory basis. First of all, we should also consider the probable overlapping with other ground-receiving stations in the sense that non-regulatory is proceeded in the Pacific Rim Telecommunity. But Considerably the Global Telecommunications for Integrative results, then we have to go into a Telecommunicational consultative for "nodal" strategic locations and dispersives mobility of the Telecommunications needs of such countries whether small or big, underdevelop or developing countries. In regards with Pacific Rim Telecommunity we fairly believe[3] "Iridium" can be a resounding success as long as the two-way system is being program on the ISDN for Global networking and "Program" management is being centralized for dispersal of reliable and "true" information technology in relation to the effect and results for the formations of a roaming information for local mobile service areas.

2.2 Telecommunicational Mobility Improves the Pacific Rim Hemisphere [4]

Cultural Growth and Development

The Improvement now in Satellite "cellular" telecommunicating has brought about the bridging the gap of have and haves-not countries in the Pacific Rim Hemisphere cultural growth and developmental objectives. In my main areas of professional specialization "Remote Sensing" we are met by many difficult experiences and problems and we are raising it here in this scientific "fora" -- The compatibility of our needs/rights for the Pacific Rim Telecommunicality because of the lack of vital "amenities". In short, take this hypothetical "theory" to secure our satellite thematic "Mapping" data we make a computer search for our technical clearance record from a nearby "ground-receiving station." This would necessarily and uncomfortably take us longer than the time frame as set-up by our organization and our would be clients and service customers. This we think has ripen for us to take a bold step for the Pacific Rim Telecommunicality as well as for the people of Asia.

Now secondly, let me consider "IRIDIUM" is to make the Telecommunications with anyone at anytime --- no matter where they are --- a reality through the use of satellites. Using a handheld portable phone, callers will send signals to one of the low orbiting satellites, which will then send the signal back to the receiver's handset or on to another satellite. This would enhance Interconnectivity to emergent situations, events, places and localization on mobile systems. Now with the new capability of the "STAR" (Satellite Tracking and Reporting Sensor) which the EOSAT has provided for the answer of providing a 5 Meter High Resolution Remote Sensing Data.

This program is to fly a high resolution on Landsat Satellites.

A program of this type will combine satellite sensor, communication and data processing technologies in innovative ways to implement a new state-of-the-art information gathering capability. Now, with the STAR system the following services are possible:

1.0 Three color, 5 meter resolution images of any location in the world.

2.0 Coverage of any part of the world on a dail; basis.

3.0 Data delivered within hours of its collection for crisis situations.

4.0 A worlwide library of data.

5.0 Imagery custom-tailored to fit individual formats.

We formally believe at this juncture that our needs/rights for a Pacific Rim Telecommunicating capability here in Asia can only come into realization by installing or the installation of a Ground-Receiving station here in the Philippines such as and similar to that of Japan and Thailand.

- o transferring of calls to an operator assisted message services;
- o call transferring to a voice mail system;
- o immediate billing functions allowing temporary telephone users to be invoiced with no delay;
- o detailed billing;
- o data transmission possibility; and
- o speech scrambling.

2.3 Our Experiences and Problems as a Satellite "Cellular" Communication User

In this mobile society and how has it improve the Pacific Rim Hemisphere Cultural Growth and Development.

In Satellite "Cellular" Telecommunicating usages in this mobile society our Experiences and Problems has been the emergent "needs" and immediate satisfaction of management and user benefits in times of disasters and emergencies and actual "pinpointing" of hazards and danger points. It is also our common saying, BONUM COMMUNE, "for the greater good of mankind. Thus, preparation for the eventuality is greater for us in planning or a "time frame" is set-up by us before any project or "program" management is undertaken by us. In the event, all the safety "factors" and technical parameters are being made not by us in advanced before it recurrs or occurs so no faulty "deductions" are blamed on us, but preciseness and occurences are accrued and benefis are assigned to us. Thus Benefits as against cost is greater on the ratios will be at 4:2 or Equity is at 4% and Debts is at 2%.

2.4 Using ISDN for Satellite "Cellular" Telecommunications Integration for the Pacific.

The continued cooperation among ISDN users is necessary for satellite "cellular" Telecommunication Integration for the Pacific and to ensure the successful deployment and cost-saving use of ISDN applications and Technology. If we could considerably revolutionarize the ISDN for the successful telecommunications Integration for the Pacific then this would be a paradigm on change for the satellite "cellular"

Telecommunicality as in combination with ISDN. It is indeed very timely for us to assure the many benefits that the general public at large will gross for the ISDN challenges we are mainly targeting its goals for the Telecommunications Integrations for the Pacific Rim Regions.

ISDN Technology has indeed three general elemental bases:

- o switching nodes
- o networking interconnection
- o customer terminals

By those three basic ISDN elements is directly and objectively impacted by negotiation of standards and the availability of equipment. The many interconnecting standards such as the islands via signalling system 7 (SS7) or other switched digital service has become an objective cooperation and integration of Telecommunications for the Pacific Rim Regions during the past year has created and successfully demonstrated ISDN applications such as dial-up video and low cost Group IV facsimile, Nationally and internationally.

2.5 Radio Frequency (RF) uses in Digital Microwave.

2.6 The Combination of "IRIDIUM" and "Cellular" Telecommunicating, improves Mobility and access to Data.

Iridium and "cellular" Telecommunicating will certainly improve mobility and accessing to data that will be interconnected with a nearby ground-receiving station by the Nordic Mobile Telephone NMT or a Groupe Speciale Mobile (pan-European cellular) GSM.

More important basic telephone services, by "Iridium", and "cellular" telecommunications will now be possible:

- o Transferability of calls to another number;
- o queueing at a busy mobile telephone number;
- o Indicatability of calls commonly received;
- o conference calls with three parties; and
- o closed and united subscribing groups and prioritizing subscribers classes.

93

This are possible for add on services for "Iridium" and "cellular" telecommunications that requires external equipments.

In Microwave Radio Frequency (RF), Requesters and active bi-directional non-frequency shifting gain devices, performed signal amplification directly at radio frequency instead of at intermmediate frequency or fuseband. Radio Frequency (RF) repeaters have been used in low - to medium - capacity analoging and digital microwaving systems for extended path lenghts getting around obstructions or improving fade margins. Hundreds of the RF repeaters are installed around the world, from snow-covered ALASKA to the deserts of Oman, from the tropical jungles in South East to the rough aides mountains in South America.

Alternatives are now being considered for a final non-dropping "through" repeate in the microwave relay system are back-to-back antennas, single or double passive reflections, a regenerative repeater with two terminals back to back or an RF repeater among these choices, the RF repeater is usually the most cost effective solution for a wide range of path scenarios; it can only be installed at only 20% to 50% of the cost in a rege nerative repeater are to its low infra structure and minimal ongoing operation and maintenance costs. The RF repeater can also provide four superior performances than the passive methods.

Telecommunications 2000 in Korea: Videotex Trial and Policy Implications for the Promotion of Informationalization of Society

Gwang-jub Han, University of Wisconsin, Eau Claire, USA
Woo-Hyun Won, Korea University, Seoul, Korea

ABSTRACT

Despite government's push for the promotion of videotex in Korea, this study found that government now needs to seriously consider the shift in its focus of public policy from an unidirectional government push to a more consumer-centered marketplace approach from an evolutionary perspective. Videotex services are analyzed from comparative and historical perspectives with focus on media adoption and use. Three key areas of public policy for promoting videotex as service oriented media technology are provided.

1. Introduction

Korea Telecom (KT) plans to distribute 10,000 videotex terminals to potential subscribers in a grant-type leasing term during 1991 for demonstration of services. The demonstration videotex services will offer 40 kinds of information including telephone numbers, taxation, medicare, economic-scientific-technological data, real estate transactions, traffic situations and amusement games [1]. More than 35,000 additional videotex terminals will be distributed to potential subscribers by the end of 1991. No charge will be imposed on the use of 10,000 demonstration videotex terminals for the one year period beginning in July 1991, while only meager charges will be levied on the use of 35,000 other videotex terminals to be leased later. KT also plans to promote the increase use of PCs, from the current 1.5 million sets to 10 million in the near future. It will also increase its *Hitel*, Korean version of *Minitel*, services to reach 3 million terminals [2].

This project is based on the Revised Three Step Diffusion Plan of Data Communication in 1988: from 1988 to 1991 would be "evaluation and development of technology and supply of 100,000 videotex terminals"; from 1992 to 1996 would be "commercialization of services"; and from 1997 to 2007 will be "connection to ISDN and establishment of terminal market"[3]. Another study by the Research Institute of Social Sciences (RISS) at the Seoul National University projected a 10% of videotex diffusion during the first stage (1988-95), 30% during the second stage (1996-2000), and 90% during the mature stage (2001-2010) [4]. Considering the RISS report's as well as other studies' much too optimistic projections (see Table 1), the KISDI report argued that increase of videotex service based on the natural growth of market size would not be appropriate. Thus, the same report suggested that the videotex projection must be made based on the KT's terminal distribution plan.

However, even the free distribution of videotex terminals does not necessarily guarantee a successful adoption of the service by consumers. Instead, the history of media adoption and videotex experiences in most pioneering countries have shown that electronic communication is less the evolution of technical efficiencies in communication or market drive, than it is a series of arenas for negotiating issues crucial to the conduct of social life [5].

It was only a decade ago when videotex was a central topic on the policy agenda of telecommunications in many countries. Most videotex projections were optimistic until the mid 1980s [6]. The notion of technological determinism has been popularly used by government and industry to generate acceptance of innovative products.

But the initial enthusiasm seems to disappear today after a number of national trial and errors. While European videotex systems have been frequently touted as successes [7], they are not the glowing success that many would like to believe. Only *Teletel* in France has often been quoted as an exception in terms of subscriber numbers [8]. When it comes to accounting its social impact, however, even the *Teletel* system is considered as 'still very limited' [9]. In the US, videotex has shown very slow but steady upwards trends in subscription based on the free market philosophy that has allowed other mass media to prosper.

In the context above, what will be the most important role of the public sector in promoting informationalization of society? Our recommendation for Korean public policy is to take an evolutionary approach with a unique regulatory scheme which is based on cooperation. In order to provide evidence for this recommendation, we will first overview videotex services and some selected studies on videotex

developement in Korea. Second, we will explain why Korea must take an evolutionary approach. And finally, three recommendations for public policy will be provided in order for the government to promote the informationalization of Korean society.

2. Videotex[2] in Korea

2.1 Overview of Videotex Services in Korea

The number of subscribers to on-line electronic information services in Korea is expected to reach 200,000 by the end of 1991 [10]. *KETEL*, the largest information distributor of its kind in Korea, now leads other vendors with 110,000 users, followed by DACOM with 22,000. Competitors, however, were insisting on a commercial base business, each with a mere 50-500 users. The number of information providers (IPs) increased from 72 in 1987 to 154 in October 1990.

While private information distributors have to rent telephone lines for non-voice service at a monthly cost of approximately $150 -$1,000 per line, *KETEL* has been offering its products free of charge from the beginning of its business in 1985. According to a report by the Computer & Communications Promotion of Korea, only 2,000 computer users out of some 150,000 password holders can connect to the computer services simultaneously.

In accordance with the popularity of electronic information services during the last few years, the number of PCs reached 1.5 million sets at the end of 1990. This represents an increase from 1.8 sets per 100 people in 1989 to 3.6 sets in 1990. At the same time, the number of computer journals also jumped up to more than 20 kinds during the last three years [11]. The production of modems also increased to 80,000 units in 1990 from 35,000 in 1989.

The subscribers' connection time to *KETEL* for the first nine months of 1990 reached about 3 million in aggregation [12]. Information searching time by *KETEL* users during the same period averaged 765 seconds. An user survey by KISDI in 1989 revealed that the average membership fee was about $70; that average access time to the service was 3.2 times per month; and that the average cost for each access was approximately $8.00. Access to economic/ business information comprised 56.4%, followed by general information (17.3%) and cultural information (10.9%). *KETEL-BBS* (Bulletin Board System) has been offered since August 1991 without surcharge by the *Korea Economic Daily*, parent company which also provides *KETEL English* databases.

DACOM has been providing *Chollian I* videotex service since 1986 temporarily and *Chollian II* since 1988. Some 9,900 subscribers of DACOM's *Chollian II* used computer aided health diagnosis service 27,831 times in June 1991, which means that *Chollian II* subscribers' average access time to the health service was 3 times per month [13]. *Chollian II* subscribers can also select their own subjects based on school curriculum via PCs. The contents of this educational service are changed and updated every two weeks. They can compare their educational level with others in the same district or nationwide by taking regularly scheduled exams with surcharge of $14.00 per month.

According to a 1991 survey research among 768 subscribers of *Chollian II*, 84% of the respondents replied that the service was helpful to their school performance, of which 77% reported improvement in one area of subjects, 44% in two areas. The most popular subjects were English (34%), followed by mathematics (32%), and Korean language and literature (28%). Over half of the respondents (54%) accessed to the service 2-3 times a week, 23% 4-5 times a week, 58% spent about an hour as average per access [14].
KT has experimented a *Chollian*-like service in Seoul area and plans to expand its service nationwide for free until 1992 and then to charge approximately $15.00 per month for the service. KT's *Hitel*, originally designed to mimic *Minitel*, is being aggressively pushed to reach 3 million terminals. In April 1990, Dong-Ah Computer of Korea signed an exclusive *Minitel* supply contract with Intel Matique, an affiliate of the French Telecom, and the Korean firm has conducted a test run of *Minitel* in 1991 to put in commercial operation [15]. About 40 Korean users, such as private enterprises and individuals, were utilizing Dong-Ah's *Minitel* test-run service. When the service is put into commercial operation, Dong-Ah plans to charge some $1 - $2.50 per minute for its service.

Currently, electronic mail services are provided by KETEL, DACOM's PC-Serve, Koreanet's Infor-Serve, and PosData's Pos-Serve. PC communication users pay approximately $14.00 for membership fee for the PC-Serve and 2-3 cents per minute for the access. While KETEL does not charge for the membership or access to the electronic mail service, 70 cents per minute is charged for the English version of KETEL and 45 cents for the trade information service. PosServe has no membership fee but charges 3 cents per minutes for the basic service with surcharge of information service.

In addition, Korean Broadcasting System (KBS) started its regular teletext service in August 1990 after 24 months experimental broadcasting. The Munwha Broadcasting Company (MBC) started a similar service in 1991. Three local TV manufacturers introduced five different TV models with built-in decoders with the price range of between $700 and $1,000.

96

2.2 Videotex Forecasting and Research

In November 1991, as was in 1990, KISDI urged the government to continue to invest in the information and telecommunication industry in an effort to foster the industry as a strategic industry. The institute projected that the information and telecommunication related manufacturing industry in 2000 is expected to grow 100 percent from 1985, while telephone services are likely to emerge as a high-value added industry. At the same time, the Government intended to get a five percent share of the world information industry market by 2000.[3]

In accordance with the measures, the government plans to establish a national main computer network by 1996, to supply 10 million units of computers, and to train 10,000 information and communication technicians, both by the year 2000 [16]. To support domestic communication and information industry, the government plans to invest a total of about $265 million during the period of 7th five-year socioeconomic development plan (1992-1996). In July 1991, it was reported to the National Science-Technology Advisory Council that the Communications Ministry plans to pour approximately $6.7 billion into research and development projects for the information and telecommunications industries through the year 2000.[4] KT spent $180 million in various R & D projects earmarked for 1991 [17].

In this context, a series of studies and trials for the acceleration of videotex diffusion in Korea have been initiated by KT, KISDI, ETRI, and DACOM since 1982. As Table 1 shows, the rosy projections by most research studies seem to have followed the rhetoric of new technology in many other pioneering countries during the late '70s and early '80s. While it is true that Korea has come a long way in a quite short period of time in telecommunications, it has been achieved in hardware sector not in software area.[5]

3 Videotex 2000 and Beyond in Korea

Considering the practices in media diffusion in general, the speculation of videotex adoption in the year 2000 in Korea needs to be conservatively reevaluated for three reasons. First, the ability of Korea to offer new services in such areas as videotex and data communications is still very weak. Second, the consumers response for the possible adoption of new media needs a more careful interpretation. Finally, there has been a cultural lag in technology diffusion. We will discuss these three areas with emphasis on a historical aspect of media diffusion and lessons from videotex experiences of some selected pioneering countries.

3.1 Weakness in Software

While VAN market in worldwide including Korea is expected to rapidly grow (Table 2), Korea's capability to provide information services is very limited (Table 3). For example, in 1988 domestic revenue for VAN services marked Won 6.4 billion ($8.7 million). In 1990 it hit Won 15.6 billion ($21.1 million). According to a recent survey by the Information Communication Promotion Association in Korea, 80 information producers provide 115 DBs during 1991 [18]. More than half of the services began to be provided after 1990. Considering that the majority of the 65 domestic databases shown in Table 4 were developed by most government branches for their own purposes, commercialization of them is far away from now on.

Currently, 44% of the services are free of charge. However, a significant number of users discontinued the service after DACOM decided to charge for the access to *Chollian* service. *KETEL* also worries that a considerable number would discontinue the service if they charge for the access. This means a weak base of videotex users. Unlike manufacturing capabilities (i.e., hardware orientation) which have led Korea as one of the leading world traders, service areas which depend on software or service are not likely to be pushed in such a short period of time. Development of software area takes longer than that of hardware whether in information or in entertainment. Professor Porter at the Harvard University also pointed out the weak base of software industry in his discussion of promoting Korea's telecom industry [19].

In contrast, the number of Korean firms using DB obtained from abroad rose 50% from 1,420 in 1989 to 2,130 in 1990 [20]. The heavy reliance of Korean firms on foreign DB services stimulated foreign DB service companies rush into Korea, especially Korea's DB market open on July 1, 1991. Some 20 foreign DB firms are now moving from their indirect to direct on-line services through their agents in Korea. Of these, BRS and EMIS of the US and SDB of Australia have already conducted market surveys in Korea to prepare for their direct services in the country [21]. During the mid 1991, Independent Publication of the US also concluded an agency contract with Samsung Trading Co. to provide its NEWS-NET services, including 500 newsletters covering some 39 countries [22](see Table 5 for more information).

At the same time, media history has shown a correlation between hardware versus software industry. Once any medium technology is introduced into a market, the space or

An international comparison of the videotex forecast is interesting. As Table 6 shows, the forecast were quite optimistic in most countries. The Germans, for example, were aiming for a potential market of 3 million subscribers by 1990 and up to 8 million by 1993. In 1990, they actually reached 250,000. The number of IPs even declined from 4000 in 1985 to 3,300 in 1989. In Britain, more than 10 million would subscribe to videotex services in 1989. A 1990 figure was still 200,000 even including non-BT subscribers. The almost 6 million of *Teletel* service in France should have 30 million subscribers in 1990, if the projection was correct.[7] (See Table 6)

In the US, AT&T projected during the early 1980s that 7% of American public would subscribe to videotex services by 1990 [36]. Another study by the industry estimated that by 1995 about 20% of all households in the US will have adopted the service [37]. Most projections for the US videotex in the table 5 were similarly optimistic when they were made. According to the Videotex Industry Association estimate, however, the number of videotex users in 1988 was some 700,000, or 1.1 percent of US households [38]. The number of videotex customers is growing about 30% a year - to 1.3 million in 1989, reflecting increasing use of home and office computers [39]. A recent issue of *Business Week* (June 17, 1991:112) estimated that about 2 million Americans subscribe to on-line services, with passing the 1 million on *Prodigy*.

3.3 Technology and Cultural Lag[8]

3.3.1 Media Literacy

Patterns of media progression generally follow the EPS curve - grown from *e*litists to *p*opular to *s*pecialized [40]. The growth is slow due to initial technical difficulties when a technology is new. Once the difficulties are overcome, however, growth in performance and market acceptance is often rapid, then followed by a slow curve again. This S-shape process can also be seen from a life cycle perspective in economies, business, and products within them, like people and all other living things [41]. In the first stage of media development, only the elite are literate (i.e., media literate) and can afford to obtain messages from all media. Once the first stumbling block is broken, 'mass-mass' media dominate the second stage, in which content is designed to appeal to the great majority of the population based on the 'lowest common denominator' principle. The final stage of the EPS curve requires four conditions: widespread higher education (literacy), an affluent population, available leisure time, and significant population size (See Figure 1).

Videotex adoption is more likely to be the specialized stage of the model above from the beginning. Particularly, if the concept of literacy is broadened to include other media than printed text, it would seem that there will be a continuously increasing sophistication of multimedia literacy even among the haves and the learned. While videotex is likely to follow the overall developmental *S* pattern in its process of adoption, a refinement of the diffusion theory was suggested with minor modifications.[9]

3.3.2 The Chicken-and-Egg Problem

All of the new communication systems including videotex have at least a certain degree of interactivity. As an extreme example, the first adopter of telephone which is an interactive technology has zero utility until a second individual adopts. This critical mass dimension of the interactive communication technologies is a crucial factor in their adoption and use. In addition, the control of mass communication systems usually moves from the message producer to media consumer by providing an exchange capability of special message with each individual in a large different information from an interactive communication systems. This implies that IPs provide a variety of services in order to satisfy the fragmented consumers.

However, it is hard to determine the needs and wants of videotex services in the future because demand formation is an interactive process where user preferences are interdependent and collective learning is involved [42]. In other words, videotex development is on the one hand an interdependent process where the 'user value' of the system depends on the size of the user community. On the other hand, it is a collective learning process where late adopters learn from early adopters because users have to get acquainted with the system, discover or even invent new applications [43].

This interactive process can lead to the famous chicken-and-egg problem, which is often located in the start-up phase of the system. Subscribers of videotex will buy terminals only when there is already a certain critical mass which make the communication network interesting and useful. Terminals will only sell large quantities only if there are large economies of scale. The information providers will also spend major money only if they expect that there is a sufficient size of user community.

In addition to the actual use of videotex service, adoption of videotex terminals is also contributed to the chicken-and-egg problem. Assumptions about the type of videotex terminals were different from country to country. Initial thought in Britain was that the TV set with a special decoder would be the typical display device. Despite the more technical options

time of the medium must be filled up with different form of information. For example, the recording industry was the prerequisite for the development of FM radio, as movie industry was for TV, which have helped further the cultural dependency of developing nations on more industrialized countries. Video cassette recorders took off when variety of programs for playing (rather than recording from TV) became available during the mid 80s.

Japan, despite its economic super power, is still struggling to develop software industries whether it is in the entertainment sector or information sector. Recent buy-outs of US recording companies and movie studios by Sony and Matsushita are good examples in entertainment area [23]. In the information sector, Japanese revenue from the database business accounts for one fifth of the US, the number of IPs one tenth, and number of producers one twentieth [24]. In addition, both language and economies of scale would further delay the promotion of information service in non-major language speaking countries no matter how superior in hardware technology.[6]

3.2 Market Research for Videotex

Survey researches in Korea have demonstrated that ethos of videtex has not been established among the general public [25] or even among journalists [26]. According to a survey research among 506 telephone users in Seoul area during the period of June 1988, 38% of them responded that they would be willing to use electronic directory service (EDS) even if they have to buy a computer, 15% would be willing to pay a telephone fee for the new service *if* computers are installed free of change; 34% would like to wait and see, and 8% would not be willing to change from the print directory to electronic directory anyway [27].

While this response was positively interpreted in the report, further analysis implies that general consumers are not yet ready to adopt this new technology. For example, while those who have some experience with computing comprised 54% of the positive group (i.e., willing to subscribe anyway), those who have no experience of computing accounted for 35% of the same group. It is a significant difference between the experienced respondents and the non-experienced ($p>.05$). Major reasons for the 'hesitate' were "don't feel the importance of information" (35%), followed by "too high extra expense" (27%) and "uncomfortable with computing" (24%). When it comes to considering the limited numbers of the general public who know how to operate even typewriter, and the sample was collected from Seoul area which is the center for every sector in Korea, this finding needs to be more conservetively interpreted.

A 1990 survey among 200 professionals in various areas also found that public relations in "creating information mind and culture among the general public" was the most significant project among the various policy agenda for promoting informationalization of Korean society [28]. In another KISDI study of 1989, respondents showed their primary interests in unique/special news which is unavailable from other media. Then, videotex consumers want to have constantly up-dated data which can help their economic and business interest which is more towards business rather than general consumers [29]. Despite the positively interpreted responses by different studies, the demand for videotex service until August 1988 was so limited that KT announced its plan to pour Won 1,200 billion by the year 2007 for promoting the service [30].

These studies should not be regarded as exceptions when it comes to considering the previous studies in pioneering countries. Evaluation of videotex *Gateway/Viewtron* indicated that the test families used videotex as much or more than conventional media forms, and more than half of the homes accessed and used the service for more than 30 minutes each day [31]. According to the "*Viewtron Newsletter*," 68% of 200 households involved in the original test of *Viewtron* purchased at least one item through the system. On the other hand, fewer than 1,000 items were purchased in the 14-month trial. This ostensible need of individual did not necessarily drive their choice of medium.

Further, innovators and early adopters may reveal uses not expected or apparent to researchers. The open character is particularly apparent in the case of the basic communication technologies, the telephone, the computer and the electronic messaging network, which offer a means of control or communication, while leaving the end for the user to define.

For example, sociability as a major use of telephone had not been a taken-for-granted fact when early advertisers suggested this technology as an extension of telegraph which had been mainly used for business and household management. The telephone as a means for 'trivia gossip' was not envisioned by the industry but was invented by the users [32]. Similarly, the *messageries* in *Teletel* had not initially been foreseen, but was invented by the users [33].

This noble application was outside the bounds of the producers' and researchers' expectations for use of this new service. In other words, videotex has been caught between its conception as a vehicle for public information, its role as a medium for commercial transaction and its adoption as a public message board [34]. This process is referred as 're-invention in diffusion theory' which means "the degree to which an innovation is changed or modified by a user in the process of its adoption and implementation" [35].

of other countries which launched later, two compelling ideas had led to the overly sophisticated and complex display standard (i.e., a more sophisticated display standard and a more decentralized system would make the services more acceptable for private households). In Germany, these ideas resulted in many additional 'technical snags' in the terminal business and the system architecture [44]. In Canada, *Telidon* technology was a 'cornerstone' for the standards defined in North America with high quality graphics with 240 x 320 picture elements (compared with 60 x 80 for the British traditional videotex). In Japan, *CAPTAIN* (Characteristics And Pattern Telephone Accessed Information Network) was specially designed to solve the problem of 3,500 Japanese characters as well as roughly 120 Latin symbols and alphanumeric characters. Result: all the sophisticated terminals have shown very limited acceptance by the consumers in each country.

In contrast, French telephone subscribers were to receive a simple and integrated compact terminal (i.e., *Minitel*) free of charge from their PTT as a substitute for the telephone book. The *Minitel* could also be used for other information services and whose diffusion was under the PTT's control [45]. The French did not concentrate on graphics display as we see in Canada, Germany, Japan and the US but had other advantages - a full range of tested software and hardware that was easily taken to market. While the free distribution of terminals has been related to the 'French success,' high diffusion rate of terminals does not necessarily mean 'frequent use.'

In the US, there is no government mechanism for developing a nationally coordinated videotex system. But the US industry also believed that graphics were more important as an integral part of the technology and therefore would be more important to the consumer. AT&T's NAPLPS (North American Presentation Level Protocol System) was formally approved by the American National Standards Institute in 1983. However, potential users in the US bought PCs (ASCII) instead of dedicated videotex terminals. *Gateway* and *Viewtron* encountered tremendous marketing resistance to the AT&T's *Septer* terminal costing $900 [46]. By the mid-1980s, attention shifted to creation of software that let subscribers transform their PCs into videotex terminals. PCs are less sophisticated in graphics but faster than NAPLPS with more functions. Thus, PCs and software are being designed for better color and graphics as a result of the evolution of videotex into use almost exclusively with PCs [47]. Among the over 20 million PCs users in US homes, there is a market of 1.7 million videotex subscribers with perhaps 450,000 'hardcore' users," if we adopt Arlen's '25% pyramid.' According to Arlen, "25% of US homes have computers, 25% of those have modems, 25% of modem owners subscribe to online services, and 25% of subscribers are frequent users [48].

3.3.3 Entertainment Value over Information Value

The real determinant of what sort of videotex service makes sense is the information it provides in relation to the needs of the consumer. While videotex has much higher information to entertainment ratio than most media, information is not a high priority for the consumer [49]. It seems common among the general public that entertainment is more valuable than information or education crossculturally as well as historically.

Videotex is perceived as a consumer-oriented product because of the relative popularity of the *Teletel*. However, consumers use *Minitel* as a "screen based telephone, to communicate with other people, not to retrieve information" [50]. More specifically, the *'messagerie'* service accounts for 8% of calls, 22% of revenues of total *Minitel* time. In contrast, electronic directory service is providing 18% of revenue from 33% of calls [51]. In addition, *Funitel* was rapidly climbing up to $7 million a year. Callers were playing blackjack, requesting psychological questionnaires to assess compatibility with a loved one, or playing transnational chess with another partner. In other words, the key to all the robust activity in the *Teletel* seemed to be a high degree of entertainment-oriented interactive services rather than static pages [52].

Consumers' 'fun-orientation' in their videotex use was already found in *Prestel* in Britain, *Captain* in Japan, and *Gateway* trials in the US. The *Captain* system, for example, showed that amusements and hobbies were accessed 52% of the time, following at considerable distance were education and culture (14%) and sports (9%). *Teletel* 3V revealed that news and entertainment information was the undisputed leader in accesses. Bringing up the rear was education. In *Gateway* trial in the US, asked to identify essential components of a future services, 79% of a select group of likely subscribers listed games as the most essential [53]. The Computer Memory Project at Berkeley, California found uncensored sex jokes at the rate about fifty a day [54]. A large volume of jokes were also carried on ARPANET, a bulletin board for defense research contractors provided by the US Department of Defense.

In short, the users of computer bulletin boards, just like everyone else, like to have fun. Then, 900 sex-phone service can be extended to videotex services naturally as a good business. Now, Prodigy does not post messages that it considers obscene or irrelevant, while *CompuServe* and *GEnie* let members freely create much of it. Of CompuServe's many chat channels, the ones labeled Adult and Alternative Lifestyles are the busiest [55].

Finally, media history also shows consumers' preference of entertainment over information. As Table 7 shows, it took about 5 to 10 years for the popular entertainment media such as radio, TV and VCRs to reach 30% of the public, compared to 20 to 30 years of the information media such as telephone and computers. It takes about 40 years for television to reach 98% of the households, while it takes for 100 years for telephone to reach 93%, even though it has been subsidized by the government. The television industry itself suffered in the early days from lack of programming and crude presentation but it lived to become the highest consumption medium ever with the quality of convenient, cheap, and 'novel entertainment.' "Knowledge was ornament rather than necessity" [56]. And this is unlikely to change in the short term.

The preference of entertainment value over information leads to another concern – business versus residential use of videotex. The recent revival of videotex interest can be attributed to more business applications. The videotex would be dominated by business users because of information delivered to businesses rather than homes, and because there is little evidence to show that homes want or can afford videotex.[19] Business customers are willing to pay for goods and services that save time and money. Thus, videotex was seen as a means of corporate communication with employees and customers that could create or enhance a competitive advantage [57]. Personal users also value time and money but in addition seek entertainment, physical security, and alternative ways spend large blocks of leisure time. It is the difference between a specialty market and a

mass market which are kept apart by lack of compatibility. The failure of residential users to embrace the instrumental aspects of *Prestel* as well as *Captain* led to the shift in its marketing toward business users.

The early history of telephone usage is largely the story of how commercial and professional communities adopted the new means of communication. The telephone tended to be the monopoly of American businessmen in its first decade not only because they often simply substituted it for a telegraph but also they could afford AT&T's high rates better than most other Americans [58]. The telephone was a boon not only in the organization of industrial and manufacturing activities but also in the vacation industry and hotel industry. By 1900, for example, practically every large and medium-sized hotel and many small hotels had telephones in every guest room. The trend toward a telephone in every American home started when the rapid roads of the telephone into the industry reduced the cost of service substantially. Social use of telephone began to be accepted by the public almost 20 years after Bell gave a lecture in 1877 that his invention would enable people to socialize at a distance.

3.3.4 Media Quality and Functional Alternative

Furthermore, audience choices themselves are linked to *media characteristics*. Each mass medium has particular qualities or attributes that lend themselves to particular types of appeal [59]. Print media are strictly visual. Thus, magazines and newspapers are designed to catch the eye, through color, pictures, headlines, drawings, and even the size. Messages transmitted by radio involve sound alone, while TV and movies are appeal to both sight and sound.

In their process of adoption or use, people not only compare cost but also account such functional advantages as convenience, portability, time flexibility, indexability, method and speed of distribution, content, permanence, interactivity, and personailizability etc. Videotex has emerged not as pre-given wholes but rather as sites of contest for different uses, interests and visions. In fact, mass media do not appear overnight, of their own volition, for no good reason. With the appearance of each new medium, existing media have had to adapt during period of uncertainty based on such medium qualities. Videotex is just a new comer (see Table 8).

Consumer information gathering is less often purposive information seeking than recreational browsing, which affects the choice of medium [60]. In this sense, it is difficult for videotex subscribers to know what they are choosing from - the 'big picture' of the day's news, i.e. it is non-indexable. Further, videotex requires some degree of interaction to control or at least access to media – typing or pushing buttons. Thus, retrieval remained cumbersome compared to competitive print media – newspapers and magazines. In addition, electronic text is much less portable than its printed counterparts. Despite being comfortable with the PC medium, loyalties remain for traditional print media [61], especially in the enjoyment and social connection areas [62]. Media habit played a role inspiring these loyalties [63].

Now the newspaper industry understands that videotex service is not an electronic newspaper but a computer-based new electronic product in the US.[11] However, they thought videotex would pose a competitive threat and, therfore, entered the market as a defense. Videotex technology forced on the consumer does not justify his paying of 100 times the cost (on a per-word basis) of the conventional, universally acceptable newspaper [64]. Sears did not see tele-shopping replacing catalogs in the *Trintex* trial, saying the mass audience was still dubious about electronic technology and would not have it forced on them [65]. French consumers often preferred using paper directories: while over 60% of *Teletel* users requested paper directories, 92% quote the directory service spontaneously when asked what services they use [66].

In the sense above, videotex industry must have incorporated consumer needs and uses into the existing format as the *Teletel* emphasized videotex as an extension of existing services rather than as a new fancy service in its introduction. In fact, videotex services emerged as little more than an alternative delivery mode for a few of the traditional products of banks, retailers, and the media [67]. For example, a content analysis of *Viewtron*, *Gateway*, and *Keyfax* found that a majority of stories came from the wire services and most of the rest from the local paper owned by the system's parent company [68]. In short, electronic news rose above "rip-and-read radio for the eyes."

Further, it would be necessary to account voice processing, facsimile service, and shopping services on cable as the functionally competitive new media in the future. Both content and format of audio communications need to be brought into considerations of the future of videotex [69]. In fact, we are still in a predominantly voice world today. Despite the high-speed digital technology in the network, anything from 6 to 12 times as much voice is processed today compared with other services [70]. While researchers have not spent much time on format aspects of audio communication, voice processing is spreading.[12]

Audietex is an easy and fast way of find information. By dialing hundreds of numbers, a caller can receive a customized information from a computer 'voice' instead of watching it on a television or computer screen. Voice processing may be a competitor of videotex, especially when ordinary PCs turn into voice systems. Pacific Telesis planned to introduce its own gateway in San Francisco in 1990 by concentrating on audiotex services, not on videotex, despite a bountiful, home lease of high-tech companies in the area [71].

Beginning January 1990, the *New York Times* began publishing *TimesFax* targeted to Asia. By 1991, the *Los Angeles Times* plans to launch *NewsFax*, a four-to-eight page faxed newsletter targeted to Moscow [72]. In Japan, facsimile broadcasting offers information promptly and permanently in the form of hard copy. Speed and permanence have never been simultaneously offered by any traditional media. It is widely believed to be the third most important media after newspapers and TV broadcasting [73].

The cable home shopping was not the accepted approach to advertising when the Home Shopping Network (HSN) began in 1985 [74]. The apparent success of television shopping programs was believed to be a threat to turn cable and independent broadcasting into a 'giant flea market.' In 1989, HSN with 60 million subscribers and QVC/CVN with 37 million marked over $2 billion revenues [75]. According to Kathy Jurado, HSN's vice president for corporate communications, "We serve a dual purpose – shopping with entertainment value – while videotex services are more of an information service, a 'still life' service."

4 Policy Recommendations

4.1 Unique Public Policy with Vision for the Long Term

There are three strategic areas for improving competitiveness in telecommunications in Korea: establishment of integrated networks; providing a broader range of telecommunications

services; and be a truely global competitor in both hardware technology and services in the international market (These are professor Porter's reccomendations). In order to achive these goals, it is now important for Korea not only to just copy what other nations have done but to create its own unique regulatory climate and its own unique network based on a unique cultural tradition. A pure decisional approach would be rather meaningless without taking into account the special conditions in the different countries which changed overtime. The history of media adoption and videotex experiences in most pioneering countries have shown that electronic communication is more than the evolution of technical efficiencies in communication. It has been a series of arenas for negotiating issues crucial to the conduct of social life in a unique cultural tradition, which must be seen from an evolutionary perspective.

4.2 Regulation as Coordination: Conduit versus Content

Korea could be one of the first countries to achieve an ideal ISDN because she already makes distinction between conduit and content, and still retains government ownership of the nation's largest communication facilities. However, the separation of government function does not necessarily guarantee any successful videotex adventure. The common carrier policy in many countries did not work as planned in the development of videotex services.

A key factor for success in videotex is development of a central co-ordination mechanism. The different components of videotex system (services, network, and terminals) are developed in a coherent and balanced way so as to solve the different economic dilemmas and the technical problems inherent to large technical 'network systems.' This central co-ordination function may be performed either by public agency or private corporation hierarchy. Considering the state's politically accountable authority and greater legal and institutional capabilities to organize the cooperation between various partners, a government agency may well be best-placed to perform this co-ordination function. Again, the capability of orchestrating multi-faceted interest groups as well as the separate but intertwined government branches is essential.

4.3 Step-by-Step Approach

More specifically, the master plan must be provided based upon thorough understanding of the mistakes made by other countries and the relationship between media quality and consumers' media habit.

As the information economy is creating 'scores of niches within niches,' videotex is envisioned as a primary source of micromarkets in the long run. If the information infrastructure is completed and virtually everyone will be connected to a public electronic malls, may be between now and 2010, thousands of specialty markets may appear. However, public policy must take an evolutionary approach because specialized information will be in the domain of business rather than the residential, at least for years to come or even longer than a decade.

Therefore, promotion of computer use in business sector and higher educational institutions, computer and terminal use among government branches as well as lower and middle educational institutions must be the first step of diffusion strategy. Future users, first of all, must be media literate which required several hundred years in the print media. Compatibility between terminals and computers will be the prerequisite. At the same time, the general public needs to be educated about the technology as an extension of human being's physical limitation, and media as another extension of our sensory systems, both are natural to human's instinct. IPs also needs to be encouraged to start in business and science sectors first. The market for the general public's residential use needs to be developed based upon the experience and relatively acceptable profit from these areas.

NOTES

1 Rice & Paisley counted 50 projects in 16 countries [Rice, D. and W. Paisley (1982) "The Green Thumb videotex experiment evaluation and policy implications," *Telecommunications Policy*, 6/3:225]; Gillies reported 115 videotex in 1983 [Gillies, D. (1990) "Technological determinism in Canadian telecommunications: Telidon technology, industry and government," *Canadian Journal of Communication*, 15/2:6]; and Alber provided 22 countries. [Alber, A. (1983) *Vieotex/Teletext*, New York: McGraw-Hill, Inc.] During the late 1970s and the early 1980s many countries had similar goals and motivations for getting involved in interactive videotex. It has been recognized that telecommunications industry is one of the most crucial areas that really creates the infrastructure for economy: It provides an infrastructure for many companies; it influences a country's research activities; and it promotes software network equipment and information services. Therefore, most countries were looking for (1) an opportunity to increase PTT's revenues by providing new services which will increase the traffic in their existing telecommunications networks; (2) the new products for the time when the telephone would reach in its saturation point; and (3) the support of domestic industries in telecommunications and consumer electronics. Thus, the objective in all the countries was to reach the mass market effectively and efficiently. While this push was initiated by the governments in the European model (included Japan and Canada), it was provided by the banks, retailers, and newspaper industries in the US mainly as a defensive venture.

2 No single set of definitions of videotex has been commonly accepted in the field. Videotex, for example, is variously used to refer to a television-based broadcast information service or alternatively for any service utilizing a computer display to display retrieved text. The lack of an agreed structure and terminology makes the development of meaningful statistics difficult and also muddies the integration of different viewpoints. Videotex is defined as an interactive information service that allows individuals to request frames of information from a central computer via telephone or cable, for viewing on a video display screen usually a television home receiver [Gross, L. (1990) *New Television Technologies*, Dubuque, IA: Wm C. Brown]. However, videotex and online databases were interchanging attributes by mid 1980s in the US. Thus, the term videotex has become a generic term for systems that has interactive capabilities and provides electronic text for distinctions eliminated as the technologies merge. This definition includes not only videotex but also online databases used in conjunction with the personal computer or multi-standard dedicated terminal. In short, the overall umbrella is taken as information services.

3 A seminar sponsored by KISDI in 1990 projected that the domestic information and telecommunication industry is likely to grow 10.2 percent during 1990-1995 period and 8.7 percent in the 1995-2000 period. By 2000, Korea's information and telecommunication industry is expected to account for 7.8 percent of total sales of all industries and 8.0 percent of the value added amount in GNP (See *The Korea Economic Journal*, September 11, 1990:4).

4 According to the R&D policy directives, state-run research institutes will be encouraged to conduct basic R&D projects, telecommunications firms applied technologies, private enterprises commercialization of developed items, and colleges and universities key and fundamental technologies.

5 We are using the term 'software' as a generic term for the content-oriented industry for any media.

6 Despite the technical and economic superiority, Japanese is not yet one of the four 'technical languages - English, French, German, and Russian - mainly because Japanese is a language understood by few outside of Japan.

7 However, someone provides a different data: the projections in France were rather low and even much below the actual development. See Charon, 1987. Recited from Schneider, et al., 1991

8 Time lag between the introduction of a technology by the industry or government and mass adoption of the technology by the public.

9 For example, the critical mass theory by J. Marcus (1987) ["The French videotex connection," *Issues and Science and Technology*, 4:108-112] suggested that a successful videotex service tends to grow geometrically. According to Markus, the long-run average cost per subscriber and cost per service of a successful videotex company will decline as in the publishing industry because there is little reproduction cost in videotex. However, this analogy is not valid when it comes to considering that (1) the publishing industry itself is not homogeneous (in terms of permanence, time flexibility, and supporting structure), that (2) most popular services on videotex need to update information continuously, and that (3) combination of joint-consumption theory and traditional diffusion theory can better explain the production cost of media content. T. Bolton (1983) ["Perceptuals that influence the adoption of videotex technology: results of the channel 2000 field test," *Journal of Broadcasting*, 27:141] found the impact of perception in the adoption of videotex, which became less favorable over time. This finding is accounted by Rogers (1986:121) in his explanation of the special characteristics of new media. See [54]. Further discussion is beyond the scope of this paper.

10 For example, the results of numerous videotex field trials also suggested that consumers were not ready. It was found that 66% of the San Diego residents he surveyed were uninterested in teleshopping because shopping was a social as well as an instrumental activity. Similarly, 55% of the respondents were uninterested in home banking because of no advantage or of personal contact preference. See Ledingham, J. (1984) "Are consumers ready for the information age?" *Journal of Advertising Research*, 24/4:31-37

11 James Holley, president of Gateway, stated that "We reached the point where we learned enough to know that [videotex] was not a threat to our newspapers or our cable companies or our magazines which is what drove us into this project in the first place." quoted in Goldberg, L. (1986) "L. A. videotex outlet not profitable enough," *Electronic Media*, 30:26

12 AT&T laid the groundwork in the mid-1960s, when it began touch-tone phone service. However, the industry did not take off until the 1980s, when micro processors, inexpensive memory chips, and large-capacity disk drives became readily available.

ABSTRACT

The Telco, Cable TV and Electric Utility Industries have only themselves to blame if the affections of their loyal customers are pre-empted by whichever one of them is the first to reach the home with an all-purpose all service optical fibre. An overview is presented noting the conflicts, cooperation and confusion attendant upon creating a new infrastructure based on optical technology.

Arthur C. Clarke, a familiar figure around the Pacific Basin, is wont to castigate the current generation of technocrats for what he calls "failure of the imagination". The phrase seems appropriate when applied to the practitioners of cable television, telephony and the related services provided by the electric public utilities. Recently a U.S. regulatory commission issued a call for papers on the subject to "The Entry of Telephone Companies into Cable Television". It may have been an oversight, or a failure of their own imagination, that they avoided mention of the entry of cable television companies into the telephone business. Or of the entry of electric utilities into Both the cable and telephone businesses. Or of the intrusion of all of these three interests into each others' businesses via optical fibre in whatever configuration the law either permits or can be persuaded to permit, and however it may be integrated into the infrastructure of any given country.

It is a paradox that the advanced technological situation of the United States may present the biggest obstacle to the ultimate rationalization of its own telecommunications and information systems. In the U.S. the three protagonists mentioned above will soon approach parity in their physical and economic assets. They lobby the legislatures with great diligence, seeking advantage beyond the equal rights they are supposed to have in the developing technologies of fibre optics, direct broadcast satellites, personal communications systems and interactive broadband services. But as usual, the regulatory perceptions lag behind the laboratories and nobody seem to know what the customers really want out of all this. Until quite recently the British approach was that the bureaucracy will decide what is in the customers' best interest, but now we find that customers are deserting the biggest bureaucracy of all, British Telecom, for the newly ordained cable telephone - TV entities that are springing up all over the U.K. And the entrenched U.S. telephone companies, like the British long accustomed to giving the customer what they thought was good for him, have invaded the British cable television universe with a surprising concern that the customer be allowed to choose not only his video entertainment but his telephone service as well. In Germany, the Bundespost moves steadily ahead with a fibre optic system which includes CATV and Telephony, and the well-disciplined customers assume that this is the only way to do it. But the world is indeed changing as elsewhere the customer's voice is heard not only in demand for information services but, as in the former Communist countries of East Europe, for some useful work out of their politicians as well. The problem of how the customer is to find out what is available to him remains, as always, a strange mix of monopoly politics, governmental regulation, impatient engineers and hidden agendas in industry convocations.

The purpose of this discussion is to present the current inter-relationships among three industries which are intrinsically enfranchised monopolies, but are approaching the point where thru the technology of fibre optics any one of them could either become the biggest monopoly of all or simply be displaced by one of the others. Hitherto the principal players have been the telcos and the cable TV industry, each with access to the customer premises within a defined role. Each is building and re-building on a fibre base, in many cases right to the curb but eventually to the home, with the capability of providing all the services of the other.

The character of fibre has introduced the third player, the electric utility industry, with equal access to both customer and capital. As a non-conductive medium, fibre presents no technical obstacle to the combination of electric transmission and communications facilities in a single facility. Thus an electric utility can satisfy its communications needs and distribute its product with the same fibre cable and the same poles. Modest advances have been made in this direction involving telephone carriers but not cable TV companies.

The question emerges, will the competing interests in the use of fibre inhibit the development of a new all purpose infrastructure, as seems to be occurring in the U.S., or will countries such as those represented here with a less mature structure take

advantage of the opportunity to harmonize the uses of fibre to create the optimal information network from the technological, economic and cultural points of view. The scene in the U.S. might be reviewed with some profit to future planners.

TELCO. By the end of 1990 over 3 million fibre miles had been installed by the major long distance carriers and more than that by the Regionla Bell Operating Companies. Rebuild or overbuild, fibre is displacing copper in a series of steps that will eventually reach the home. Experiments with unused capacity proliferate around the nation with the telco in its accustomed role as common carrier but handwriting on the wall in Washington already predicts the change in telco status from common carrier to franchisee or at least to a program service. Depending on legislation, the latter may or may not have the local image or community service responsibilities normally imposed on CATV systems by franchising authorities.

Fibre technology imposes no limitations on what may be carried into the home in the future. The only question seems to be, whose fibre will do it, for while it may be economically questionable for a telco to install fibre simply for telephone and data, the same fibre loaded up with video and indeed electric power transmission might well be an attractive investment for any one of the three industries concerned. So far, the telco industry seems to be furthest ahead in taking initiatives that will lead it beyond its traditional role in response to the challenge of fibre. Proposed legislation, would stimulate that process, unless the CATV industry makes a more appropriate response that it has done to date. Fibre optics bids fair to breach all corporate borders similar to the way communications satellites breached national ones and telcos are the quickest to realize how this affects their future interests. Indeed, Rep. Edward Markey, member of the US Congress, said recently "We will no longer be able to speak in terms of phone companies, or cable companies. They will become part of a larger information industry, including computer manufacturers." His overview has not resulted in any policy proposals to integrate these industries. However, neither has it stopped industry movement toward such integration, as for instance in the southeast portions of the U.S. where telco-cable and telco-electric utilities ventures are probing into all levels of both technology and economics.

CATV. For many years the cable industry has had in place the facilities needed to provide a variety of broad-band interactive services to its customers. This was, and remains, the ultimate promise of cable. Whether due to lack of customer comprehension or lack of cable operators imagination, the promise had not been realized beyond scattered trial runs. The introduction of a 150-channel cable system in New York suggests runaway capacity but a failure of imagination concerning their usage.

The primary objective of cable has been to widen the subscriber base and upgrade the video program service provided. Interactive services, such as the Los Gatos- Hughes and Motorola experiments in California were good for convention seminars but never reached operational status or aroused consumer demand. Distribution of data and voice by cable systems was hardly mentioned until recently and cable's potential in this field within the U.S. was considered so controversial as to be possible under only the most arcane arrangements. As one regulator put it, "go ahead and do it, just don't call it a branch of a cable TV system." Better still, go do it in the U.K. Meanwhile, in pursuit of its primary mission, cable concentrated on video entertainment, launching more and more channels for less and less edifying program material. But 150 channels will surely force the issue of non-video usage.

The more recently built cable systems set about providing dual 400 mz trunk to their franchise area with the concept of using the second trunk or institutional cable, as it is called, for public institutional purposes such as schools, library networks and civil government. In many cases this I-cable has lain fallow, or has been under-utilized. Not surprisingly it has occurred to some that wherever the law allowed and the local telco failed to prevent, high-speed data could be carried on the unused portion of the I-cable both intra and interstate. In the former case state regulation, weighted in favor of telcos, has to be observed and if possible accommodated; in the latter case FCC pre-emption permitted such use, and at least one interexchange carrier has reached a workable formula for the interconnection of a cable system with its long-haul facilities; a customer base has also been defined and orders placed.

This modest beginning of a new traffic and revenue stream for cable systems pre-dated the arrival of optical fibre even on trunks. With cable system re-builds turning to fibre, with capacity far exceeding the available supply of programs and the ability of the viewing public to absorb more video entertainment, it is timely to consider what the more far-sighted cable operators have in mind as they move from trunk to feeder, to curb, and eventually, or inevitably, to home, with the broadest-band system of all.

It may, indeed, be time to hedge one's bets on the cable future. Hughes Aircraft engineers confidently predict the arrival on stream of their Direct Broadcast Satellite for 1994. Three entities with much to lose by this development, Cablevision Systems Corp., NBC and Rupert Murdoch have formed with Hughes the Sky Cable enterprise which will offer 108 channels to anyone with a two-foot dish on his windowsill. What will Cablevision Systems' million-plus subscribers do when they no longer have to tailor their monthly fee to certain packages which contain

channels of no interest to them? What will NBC do to preclude cable multiple system operators from obtaining access to its programs at the expense of local broadcasting stations? And what will program producers come up with to fill 108 channels or indeed 150, whoever controls them? Even including Pay- TV, saturation may have been reached at 75 channels, rather than Sky Cables' 108, and remember that there are at least eight other DBS applicants waiting in the wings, some with affiliated program resources, some without.

Some cable entrepreneurs are, then, hedging their future by joining the DBS, since they can't defeat it, but at the same time they and other multiple system operators are energetically laying fibre as they modernize and rebuild their systems. It would appear that with current access to 85% or more of U.S. homes the basic economics of cable has nowhere to go other than through raising rates, commercial advertising, integrated program ventures and service up-grade.

Pending re-regulation activity in Washington adds to cables' uncertainty in its entertainment business. These and other factors have had a negative impact on the brokerage of cable systems which is expected to increase. It may not be the expectation of constantly rising profits from entertainment that motivates the desire of other-than-cable interests in entering the CATV business. In view of the factors and influences mentioned above, it must be something else. It might even be the potential profit in cable combined with local Personal Communications networks, the proverbial wristwatch mobile telephone. Or it could be the vision of the all-purpose single access to the ultimate user.

ELECTRIC POWER. Enter a third protagonist, the electric utility. In the past, electrical utilities have relied on microwave for their own communications requirements. For technical reasons these companies are beginning to deploy fibre for internal use, often in cooperation with interexchange carriers, where each can offer the other certain advantages, including rights of way and joint use of high voltage transmission lines. Fibre as the first "non-conductive" medium for information transfer in large amounts, offers an irresistible motivation to future large scale integration of initially long-haul power utility and telecommunications distribution. As this development proceeds through legal and policy gestation, the shared use of fibre into the home becomes equally attractive for both economical and technical reasons. This does not mean that either party will necessarily see it as such if one or the other makes the initial installation. A joint deployment, however, may eventually be preferred to a threat of by-pass. In any case, one does not see any telcos or cable companies seeking to acquire electric utilities. Current activity seems to be limited either to mutually defensive moves or to shared use of facilities, with advantages in capital conservation and possible redundancy in the network structure.

If telcos and electric utilities seem to be either at a stand-off or shyly moving toward joint operations, they show no such modesty toward the cable industry. Their interest appears to be to invade cable's turf either by offering the service that cable now provides or by acquiring someone who does. In the case of utilities, acquisition of cable systems, such as Houston Industries buy-out of the Rogers cable systems, was initially a straight business proposition, not an attempt to merge technologies looking to a single access to customer facilities. And yet the very systems Houston acquired are already experimenting with other than video entertainment, such as energy management data distribution and interactive video services. It is reported to be a profitable undertaking and remains unperturbed by regulatory complications. Manhattan Cable has for years
provided data links for the financial community. In New England there are customers for both short and long-haul data circuits, jointly provided by a local cable system and an interechange carrier in a formula which has met competitive but not legal obstruction. The emerging pattern seems clear enough. Telcos and utilities are probably as active in the CATV acquisition game as is anybody else right now. If one asks why, the answer has less to do with the future profitability of cable alone than with access to customer bearing all the services that optical fibre could provide.

One notes that the initiatives of CATV toward common carrier type services, and similar moves by certain electric utilities, based on optical fibre, have been kept at a low profile on the public and regulatory stages. Not so the telco push to provide video program services along with its accustomed role of telephony. Certain trade publications, such as the Cable-Telco Report published by Fred Dawson, are stirring up the imagination of CATV and utilities people who are looking for new economic frontiers. And the telco themselves who have always had a barely-concealed itch to get into show-business, are riding a wave of legislative discontent with the CATV industry by suggesting that competition might solve some of the problems, and that they, the telcos, might be able to do it better. The CATV industry has not yet realized that this argument could work both ways. And the electric utilities' engineers are only beginning to perceive the operating efficiencies and investment economies toward which fibre is leading them, to say nothing about the delights of providing other kinds of entertainment to their customers and investors.

Any predictions regarding the future trend of these developments would entail the usual risk. No one entity is likely to end up as the purveyor of all services to the end customer. The already wasteful overbuild of cable TV facilities is not to be written off in favor of telco initiatives to expand into cable TV-land. Conversely, cable-TV facilities should not lie fallow for lack of a friendly marketing environment. Electric utilities, new to show business but not averse to the profit potential of new technology, seem likely to inch their way into the ring in a cooperative rather than a pre-emptive mode. In the final analysis, the factors of marketing, customer relations, capital formation and technical sophistication will determine the outcome. The predominant industry in the three-sided pattern of the future will be the one that best understands the service path to profit, and the one that is most effective in the gentle art of convincing the regulators of the correctness of its views.

The Year 1992, a period of rapid change, finds these three industries converging at a point in the future that is coming closer all the time. They are like the proverbial three men in a tub, drifting on a sea of regulations but without a rudder. The game will eventually go to the boldest, as ever, and at this stage it would seem that the telcos not only have the advantage but appear to know how best to use it. As Arthur Clarke said, "Science with its usual cheerful indifference, has laid another squalling infant at the doorstep of society." Let us hope that the regulators adopt it, and present us, not with yet another monopoly, but with a healthy new member of the family.

THE IMPACT OF NEW BROADCASTING TECHNOLOGIES ON DEVELOPMENT

Richard L. Nickelson, *Senior Counsellor*
International Radio Consultative Committee (CCIR)
International Telecommunication Union (ITU)

Abstract

The impact of several inter-related new technologies on the development of broadcasting, especially with respect to small and developing countries, is expected to be considerable. Regulatory, policy and technical elements will shape the inevitable introduction of these new technologies, in response to consumer demands. Source, production, delivery and display environments are expected to undergo major changes. The flexibility and resourcefulness of broadcasters and the broadcasting industry will determine how these changes affect them. The work of the CCIR and the CCITT is most intensive in these areas.

Introduction

Broadcasting is at the cross-roads of the 21st Century. Rapid developments in technology will enable delivery of sound and television programs to the home with unprecedented quality, and in the case of sound broadcasting, at lower cost to the broadcaster and listener alike. The consequential rearrangement and renewal of production, distribution and broadcasting facilities will create major changes - comparable to those that took place when FM broadcasting and color television were introduced.

Regulatory and legal aspects will continue to influence the rapidity with which technological innovations bring about real changes, and these vary from country to country and from region to region. But once a new technology is perfected and ready for introduction, there are inevitable pressures for change.

Important technological advances in the following areas are involved:

- High-definition television
- Satellite sound broadcasting directly to home, portable and mobile receivers
- Digital sound broadcasting
- Personal communications
- Microcomputers
- Fibre-optic networks
- Integrated-services digital network (ISDN).

High-definition television

There has been remarkable progress in the development of compressed-bandwidth high-definition television systems during the past two years. This development has resulted in a major reorientation of the activities of the CCIR, where work on developing a system standard for the broadcasting of high-definition television to the general public began in 1974, when Question 27/11 was adopted at the XVth Plenary Assembly.

HDTV has become one of the most charged issues in the international standards-setting arena. The economic success or otherwise of two other high-technology innovations, the broadband integrated services digital network (B-ISDN) and satellite broadcasting, is seen to be closely tied to HDTV, so it is of even greater importance than it would be otherwise. Present trends indicate that HDTV will be introduced into the home during a transition period that is equal to or longer than the transition period between monochrome and color television. It is likely that the B-ISDN will be widely available before HDTV is commonly accepted, but the introduction of broadband subscriber loops may take place in parallel. The B-ISDN and broadband subscriber access will also provide a friendly environment for the delivery of conventional television programs. The questions of cost and readiness of subscribers to pick up the tab have to be resolved.

Standards

The CCIR is the centre of worldwide standardization efforts in developing the HDTV system of the 21st Century. In 1985 a proposed world standard for the studio was considered based on 2:1 interlaced scanning with 1125 lines and a field rate of 60 Hz. An aspect ratio of 16:9 was proposed, requiring 1920 luminance samples per active line, and 960 color difference samples [Ishida and Nishizawa]. Awakening commercial interest in HDTV in different regions of the world led to an

alternative proposal in 1987 for a system using 1250 lines, 50 Hz progressive scanning* [Wassiczek, Waters and Wood].

There are four inter-related areas for standardization in television: studio standards, exchange standards (including recording and transmission), emission standards and display standards. Considerable benefits would accrue, particularly to the global public, if a single world-wide family of easily-convertible standards, applicable to the production, transmission and emission media (satellite and terrestrial) were available. The resulting economies of scale in the production and delivery of programs as well as in the production of receivers offer the possibilities of major benefits to all of the participating elements, from program producer to viewer and would open vast markets to manufacturers.

The XVIIth CCIR Plenary Assembly (Düsseldorf-Neuss, 1990) adopted Recommendation 709 which lists all parameters necessary for the definition of the HDTV studio signal. A few key parameters, including picture rate, remain to be agreed. Continuing conflicting interests among its members have prevented the CCIR from agreeing on a studio standard. Four other Recommendations related to HDTV, including recording and exchange standards, were adopted.

Delivery means

Terrestrial emission remains by far the principal means for delivery of television to the home. Because of lack of additional spectrum in densely-populated areas, terrestrial emission of HDTV will require considerable bandwidth compression of the studio signal.

Satellite emission means are particularly attractive to provide wide bandwidths for HDTV, and coverage of large geographic areas can be achieved very quickly. Direct satellite broadcasting using high- and medium-power satellites is foreseen as the principal means for broadcasters to introduce HDTV in those countries where broadcasting is mainly carried out on a national basis and there are few local television broadcasters.

Video cassettes and optical disk recording will be important elements in the HDTV marketplace. Home-market VCRs are in an advanced state of development, and the progress towards a read-write optical disk recorder could revolutionize television signal recording.

Cable systems, including the B-ISDN, will offer high-quality, high-capacity means for the delivery of HDTV to the home. Indeed, the economic viability of broadband services delivered to the home will likely depend largely upon television.

Regional approaches

JAPAN

Japan started in earnest to develop HDTV systems following the adoption of Question 27/11 in the CCIR in 1974. NHK laboratories had progressed to the point of implementation of a system design, including prototype hardware, by the time of the XVIth CCIR Plenary Assembly (Dubrovnik, 1986).

At that time, Japan was concentrating on developing a completely new, premium service (both in terms of technical quality and programming) for delivery by satellite. Hence, the newly-developed system did not require compatibility with the existing NTSC system.

In addition to the studio hardware (cameras, VTRs, etc.), the Japanese designed and implemented bandwidth-compressed analogue delivery systems under the acronym MUSE (***MU**ltiple sub-Nyquist Sampling **E**ncoding*). Daily experimental satellite broadcasting for one hour each day with the MUSE system started in June 1989, using the same type of receiving antenna and outdoor unit as used for satellite broadcasting in Japan with the digital subcarrier/NTSC system. The BS-2b satellite was initially used for this purpose, followed by BS-3a. Extended operations started in 1991 using an exclusive transponder of the BS-3b satellite [Ishida and Nishizawa].

In the short time since broadcasting of conventional television by satellite was introduced in Japan, using an emission format based on the existing NTSC system, it has gained widespread popularity among the viewing public, with well over a million homes receiving the satellite emissions.

Japan has made a policy decision to introduce enhanced television *(EDTV)* for terrestrial emission and high definition television *(HDTV)* for satellite emission. [Kawauchi].

EDTV in Japan must fit within the 6 MHz band allocated for terrestrial television and must be compatible with the NTSC system. First-generation EDTV includes ghost cancellation, quasi-constant

* Initially implemented with 2:1 interlaced scanning

luminance signal processing, adaptive pre-emphasis of high frequency components in the luminance signal, higher-resolution signal sources, 525-line progressive-scan display and three-dimensional Y/C separation. This service was started in mid-1989 and is now operational in most Japanese television stations.

Second-generation EDTV in Japan is under consideration in the Telecommunication Technology Council.

EUROPE

Several European countries, in adopting the MAC/packet family of standards, established a step-by-step approach in improving the technical quality of the television signal delivered to the home. Largely developed for satellite broadcasting and cable distribution, the MAC/packet formats are not compatible with existing PAL and SECAM systems and therefore require new receiving equipment. The second step in the MAC approach is HD-MAC, which will provide a compatible transition from MAC/packet systems to HDTV. There is currently a major intensive design and development effort on the part of European industry in this area, known as *EUREKA-95*.

MAC/packet broadcasting provides noticeable signal improvements over PAL and SECAM systems and offers wide-screen possibilities, but retains 625-line resolution. D2-MAC/packet emission is presently used with the high-power broadcasting-satellite service (BSS) satellites TDF-1 and -2 (France) and TVSat-2 (Germany) [Wassiczek, Waters and Wood].

The 16-channel European-coverage television satellites *Astra* carry channels intended for direct reception using the conventional PAL system. These 12 GHz-band systems generally operate with home receiving antennas of 60 cm diameter, or less. Distribution of television and sound broadcasting programs via satellite has become very popular in Europe, with a large number of programs also available on EUTELSAT and INTELSAT satellites, in addition to national and private satellites already operating or planned for operation in the near future. As in North America, most of these satellites operate in the fixed-satellite service (FSS) and their signals are intended for distribution of television and sound broadcasting programs, principally to cable systems, but numerous direct-reception installations have been made.

The Astra services are indicative of the many private operators now coming on the scene in Europe. Since the intention in Europe has been to provide HDTV as a new service disseminated by satellite and cable systems, little attention has been given to the problem of how to introduce HDTV for terrestrial emission. The advent of new terrestrial broadcasters has precipitated considerable re-thinking in this area. Although recent studies indicate that the D2-MAC system will operate successfully in the terrestrial environment with the addition of an echo canceller, the MAC/packet systems are not compatible with PAL and SECAM receivers [Schachlbauer]. Intensive work has been going on during the past two years to develop an improved PAL system, called PALplus, that is compatible with PAL. Compatibility with the conventional PAL system is maintained.

A new pan-European research project is proposed to develop techniques that can be applied to digital HDTV [Baum]. The project, under the acronym VADIS *(Video-Audio Digital Interactive System)*, is to develop technology within the framework of the Eureka 625 project for compressing the digital television signal for conventional 625-line television by a much greater factor than has been achieved until now. More than 30 organizations from 12 different European countries have agreed to cooperate to develop the source coding technology needed for all-digital television. Some European private broadcasters who wish to see digital television emission pursued more vigorously view this project as an important step in that direction. The system is to be designed to enable expansion to high definition television.

NORTH AMERICA

The direct reception of FSS television transmission first gained wide-spread popularity in North America, where a large number of 6/4 GHz band systems are available to cable system operators and to the general public. Recently, the introduction of 12 GHz band systems has enabled the targeting of specific service areas with higher-power signals, so that the home receiver antenna diameter becomes quite small. The encryption or scrambling of satellite television services, either to protect copyrights or for pay-television services, is becoming more widespread, and is now being introduced in Europe as well as in North America. These techniques are equally applicable to HDTV and most new systems are designed to provide scrambling capabilities.

The configuration of television broadcasting in the United States, which is based on local television broadcasters, depends upon terrestrial emission. Hence, much of the development work aimed at the terrestrial broadcasting of HDTV is taking place in the United States. It is essential for broadcasters to maintain the continuity of service to existing receivers. Conventional and HDTV emissions will therefore have to co-exist during a long transition period. Since available spectrum is limited in most population centres, the possibilities for spectrum-efficient emission formats have been emphasized.

Since 1982, the Advanced Television Systems Committee (ATSC) has provided the framework for the development of advanced television systems in the United States, including HDTV. The ATSC set up working groups to study and recommend standards for studio production; for terrestrial, satellite and cable distribution and for consumer displays [Hopkins and Davies].

Following the submission of proposals to the CCIR in 1985 and 1986 to adopt a single studio production standard based on the design originally developed by NHK of Japan, interest in HDTV was considerably hightened in the United States. The Federal Communications Commission (FCC) set up a broadly-based blue-ribbon industry advisory committee on HDTV.

Decisions of the FCC taken since 1988 indicate that there should be a terrestrial HDTV service for the United States and require that viewers with NTSC shall not be disadvantaged by the new HDTV service. The FCC also has stated its intention to use the existing terrestrial TV emission bands and that each existing TV licensee could be allocated up to an additional 6 MHz of spectrum. These decisions have resulted in intensive efforts by industry to develop an HDTV emission system that is highly bandwidth-efficient. Subsequent decisions by the FCC that NTSC augmentation approaches requiring additional spectrum would not be considered further and that simulcast would be preferred have served to further focus the development efforts [Miller].

Meanwhile, as many as 21 different proposals were submitted to the FCC for new systems. An Advanced Television Test Center (ATTC) was set up by the major broadcast associations, the major television networks, the Electronic Industries Association (EIA) and cable television interests to conduct tests of the various proposed systems. Canada is also participating actively.

During the time since the ATTC was formed, two major developments have served as catalysts to completely change the direction of the evolving system. The first of these was the proposed hybrid analogue/digital simulcast proposal from Zenith that used a 6 MHz bandwidth [Luplow and Fockens]. The second was the last-minute proposal by General Instruments (VideoCipher Division) for a fully-digital emission system within a 6 MHz bandwidth [Heller and Paik].

As a result of these proposals, and the perceived quality of the all-digital simulated systems, a number of proponents of new systems have either joined forces with others, or have dropped out of the competition altogether. Four of the five remaining proponent groups have modified their proposals to offer full digital emission and the fifth provides for full digital processing in both the transmitter and receiver, but with analogue emission.

Intensive work on enhancements to improve NTSC systems is also in progress in the United States and Japan [Uyttendaele], but has been somewhat overshadowed by the work on bandwidth-compressed HDTV.

Status of the CCIR work

Meetings of the Task Groups and Working Parties of the CCIR that are dealing with HDTV were held in Geneva in November 1991. While no major progress was made in breaking the log jam that has prevented agreement on a global HDTV production standard since 1986, further progress was made towards a satellite emission standard, and work started in earnest on a terrestrial emission standard.

In this regard, a draft new Question on digital terrestrial television broadcasting was drafted and proposed by Australia for approval by correspondence.

The objective of this new Question is to stimulate the CCIR studies to determine "...what bit rate reduction coding method(s) which can form a single, flexible algorithm (or small group of related algorithms) should be used for terrestrial emission". The studies are to include the "...appropriate modulation and emission methods and their relevant parameters, for the broadcasting of digitally encoded TV signals in terrestrial channels". Finally, the studies will address "...the appropriate strategies to introduce and implement digital terrestrial TV broadcasting services, taking account of existing terrestrial broadcasting services".

Once this new Question is approved, probably by the end of January 1992, a new Task Group (TG 11/3) will be set up to prepare appropriate Recommendations on the study topics. Mr. Stan Baron (NBC, USA) will be designated as Chairman.

A second development of the 1991 CCIR meetings concerning HDTV came from Working Party 10-11S of the CCIR, which deals with satellite broadcasting. Three draft new Recommendations were adopted on HDTV: *1)* Coding rate for wide RF band HDTV broadcasting-satellite service, *2)* MUSE system for HDTV broadcasting-satellite services and *3)* MAC/packet based system for HDTV broadcasting-satellite services. These will be forwarded for consideration by Study Group 11 during its meeting in May 1992, for subsequent adoption by correspondence.

Future trends

Rapid developments in digital techniques, coupled with falling costs, will allow complex image analysis and processing in the studio and complementary synthesis in the receiver, together with efficient means of long-distance transmission and broadcasting. The historical dependence of studio and receiver scanning standards will ultimately disappear.

Digital equipment is being introduced in various parts of existing broadcasting chains, much of which is in accordance with CCIR Recommendation 601 on the digital studio standard for conventional television systems. The CCIR has recognized that the long-term future of HDTV lies in the digital domain [Nickelson].

It seems unlikely that a single emission standard, either in terms of quality or technical parameters, could be developed for economical use in all applications: source and production media, delivery media, diverse users. On the other hand, a world-wide family of standards should be achievable, if the Study Group 11 approach to a unified world-wide digital HDTV studio standard is followed.

The quality of the highly-compressed digital emission systems presently under development has surprised many specialists, who, until very recently, were predicting that it would take many years to perfect such systems. Digital emission systems offer the additional advantages of better performance and superior immunity to interference at significantly lower transmitter powers, and with less complex antenna systems. The savings in installation and operating costs are expected to be considerable.

If the rigorous test programs planned for the United States and Canada during the next year verify the simulated results, then terrestrial emission of HDTV may begin much sooner than had been expected only a year or two ago.

The implications are considerable for the program producer, the broadcaster and the viewer. Early viewer tests of enhanced and high definition television equipment that produced negative results were found to use converted conventional television source signals, or inferior-quality cinema film stock. This serves to illustrate the necessity of having available a complete chain of HDTV production, switching, transmission and emission equipment when these services begin. Wide aspect ratios, whether in enhanced systems or HDTV, present new problems that have to be dealt with.

This year's Montreux symposium devoted considerable time to discussion of the impact of wide-spread use of letterbox techniques to accommodate the wide-screen format on conventional aspect-ratio displays when simulcasting is done [Reimers]. Where the majority of TV receivers have a small screen (e.g., 50 cm), the viewers may have available a picture that is equivalent to that of a 36 cm display when receiving simulcast productions that originate in the 16:9 aspect ratio. Some argue that this may serve to make the viewer more aware that large-screen, wide-screen television is available, but others argue that it will only serve to annoy the majority of viewers.

Other aspects also have to be taken into account. Television production is becoming increasingly mobile. Outside-broadcast and satellite-news gathering facilities have gained wide-spread popularity among broadcasters. The CCIR has undertaken to extend Recommendation 722 on satellite news gathering to encompass HDTV.

Impact on development

The introduction of HDTV will be a costly affair, even in the most advanced industrialized countries.

Twenty years ago, when the Satellite Instructional Television Experiment (SITE) was being prepared in India, a debate was raging in the developing countries concerning whether or not television could ever be a cost-effective medium for development. The results of SITE did not resolve that debate [UNESCO], but subsequent launch and operation of the Indian National Satellite system (INSAT) and dedicated satellite communication

systems in other developing countries have proven the utility of such systems. At the same time, color television was considered prohibitively expensive for developing countries. In spite of the costs, many developing countries, including India, have introduced color television emissions as standard.

Similar arguments are valid for HDTV. In the long run, in spite of the high costs, HDTV will inevitably find its way to developing countries.

Having decided that, it then becomes necessary to consider how the cost impact can be minimized. The experience being gained in the industrialized countries will be invaluable in this regard.

Even more so in developing countries than in the industrialized ones, television is a radiocommunication medium. The existing installations of expensive television receivers may be expected to be in use *and to continue to increase in number* for many years after the introduction of HDTV. (Monochrome receiver sales are still significant in developing countries that have color television emissions available.) Consequently, the introduction of HDTV must not disrupt the existing television system.

When color television was introduced, downward compatibility was considered mandatory (i.e., existing receivers could display color emissions in monochrome without objectionable degradation). The HDTV emission systems proposed in Japan, Europe and North America all recognize that HDTV is a new, superior quality service and therefore do not provide for downward compatibility. This means that additional emission facilities will have to be provided for HDTV, if standard TV emissions are to continue for some time. Systems that require lower power and less complex antennas are therefore preferred.

Program production costs, which are already higher for color programs than for monochrome, will again be higher for HDTV. Thus, locally-originated programs may be expected to use color and HDTV production techniques only as financing becomes available to cover the additional costs. Programming that is especially amenable to HDTV with minimal additional investment in studio equipment, such as sports contests, parades and outdoor musical performances in high natural ambient lighting conditions, will initially be preferred.

HDTV is recognized as being spectrum-hungry. To support simultaneous HDTV and conventional emissions of the same programming will require a minimum of twice the presently-used bandwidth, if the approach now proposed in the United States is followed. Previously-proposed approaches would require even more. Since television broadcasting is not extensive in most developing countries, this is seen to be a secondary consideration.

Satellite sound broadcasting

A new technology that is just beginning to attract the attention of broadcasters and the public is direct satellite sound broadcasting. Intensive work by the members of the European Broadcasting Union (EBU) and others has resulted in major system proposals and feasibility demonstrations to the CCIR and during ITU Administrative Radio Conferences.

All-digital spread-spectrum systems operating in the UHF band can provide wide-area multi-program coverage of high-quality stereophonic sound broadcasting programs. Reception in homes, moving vehicles and to small portable receivers has been demonstrated. These systems combine the wide-area coverage advantages of HF broadcasting with the quality of VHF FM-band broadcasting services, and can easily include data-broadcasting capabilities.

Similar, compatible, terrestrial systems can provide additional coverage.

The development of reliable, low-cost receivers and antennas will be an important element in implementing these systems. Considerable development work has already been done, but additional improvements will be beneficial.

Consideration of the allocation of a band for this service is on the agenda of the 1992 World Administrative Radio Conference that will be held in Spain. Similarly, the allocation of a band for the world-wide satellite broadcasting of wide RF band high definition television is to be considered by that conference.

Impact on development

Sound broadcasting from satellites direct to fixed, portable and mobile receivers offers the advantages of both HF and FM sound broadcasting, (wide-area coverage and high quality) but without the disadvantages of either (very poor quality and limited coverage area, respectively).

Members of the EBU are enthusiastic about the possibilities offered by this new technology to provide continent-wide coverage of high-quality

broadcasting services. This will enable listeners to receive their home programs wherever they travel or live in Europe.

Great potential also exists for developing countries to provide national sound broadcasting coverage in a very short time frame for information, education and entertainment programs without developing the costly and extensive broadcasting infrastructure now required. Systems are already being proposed that will offer service to a number of broadcasters from a common space station [Samara].

Status of the CCIR work

The meeting of CCIR Working Party 10-11S in November 1991 approved a draft new Recommendation on digital sound broadcasting to vehicular, portable and fixed receivers for the BSS (sound) in the frequency range 500 - 3000 MHz to be forwarded for consideration by Study Group 11 during its meeting in May 1992, for subsequent adoption by correspondence.

Personal communications

Personal communications is a new technology that potentially may have more impact upon broadcasting, as we know it today, than any of the other new technologies. The convenience, potential low cost and consequent universal availability of personal communication stations will place an enormous demand on the radiocommunication spectrum. Frequencies that are most advantageous for broadcasting are also highly advantageous for personal communications. Demands are already growing rapidly, as evidenced by the decision to hold a World Administrative Radio Conference in Spain in the first quarter of 1992 to deal with a number of mobile radiocommunication issues. The combined consequences of fibre optic ISDN networks and personal communications could result in major changes in the way sound and television programs are delivered to their audiences.

Microcomputers

Microcomputers have become a part of everyday life in most businesses and educational institutions and are found in many homes. Since video display units used with microcomputers and television displays have many common aspects, the digital world of the 21st Century will witness a continuing convergence of the system design and manufacturing technologies used to implement these displays. The use of the same display for the two different functions will not be universal, or even common, by any means. HDTV, in particular, will demand large, wide-screen displays with a diagonal dimension of one metre or more, whereas microcomputer displays, which are used at much closer range, will generally remain modest in size. Nevertheless, economies in production and flexibility in use will tend to encourage the development of displays that function well in both environments.

Fibre-optic networks

The dramatic improvements in the cost-per-bit of information carried on fibre optic systems that have occurred during the past 10 years continue. The quality of such systems sets the standard towards which other, competitive systems, strive. Where costs and quality improvements are advantageous, the industrialized countries are rapidly replacing copper-based coaxial cable networks, microwave and satellite links with fibre-optic systems. The next step in the chain - the link to the home - has been technologically feasible for some time now, but cost and regulatory considerations have delayed its introduction.

To be cost-effective, the fibre-optic subscriber loop will have to carry broadband services, i.e., television. On the one hand, general introduction of fibre-optic subscriber loops carrying broadband services will completely change the concept of broadcasting. Complex issues of competition, sharing of revenues, and even the fundamental way in which programming is prepared, distributed and viewed will have to be addressed. On the other hand, and assuming eventual wide-spread availability of fibre-optic subscriber loops in national telecommunication networks, significant numbers of viewers and listeners will never be reached by this medium. This is especially true in countries with large geographic areas, in areas of sparse population density, and in areas of difficult, unfavourable terrain.

The issues affecting fibre-optic systems are inter-related with several of the other new-technology areas.

Integrated-services digital network (ISDN)

1991 marked the bicentennial of the communication protocol, for it was in 1791 that Claude Chappe conceived and built the first optical telegraph in France, which included procedures for exchange of messages between the operators to provide for flow and error control. It is quite appropriate that we take note of this advance in technology in the service of mankind, just at the

dawn of the era of digital telecommunications – as exemplified by the integrated services digital network (ISDN).

Strictly-speaking, the ISDN can use any of the available carrier technology media - coaxial cables, fibre optics, microwaves, satellites. Recently, emphasis has shifted from implementation of the ISDN to the broadband ISDN. In this context, fibre-optic technology becomes even more attractive. Advanced microwave and satellite systems will also provide major links in future B-ISDN networks. Whatever the technology used in B-ISDN networks, the enormous capacity and flexibility available will enable unprecedented possibilities to exchange and distribute television and sound broadcasting programs, and to deliver them selectively to broadband subscriber drops. In this context, it will be possible to originate television and other broadband services from any point within the network where two-way fibre-optic subscriber loops exist, thereby vastly widening the possible sources of television and other broadband services, when compared with today's network.

Conclusions

High-definition television, satellite sound broadcasting, data broadcasting and other new capabilities that will be available in the world of broadcasting in the 21st Century will develop in delivery environments that may be considerably different from those that have been used since the inception of broadcasting. Rearrangement of production and delivery means will have far-reaching consequences in the broadcasting industry, and indeed in telecommunication and computer industries, as well. Regulatory environments will affect the timing and extent of these changes, but the pressures resulting from the combination of available technology with consumer demand will eventually result in major rearrangements taking place, as has already occurred as a consequence of the introduction of video recording and satellite transmission technologies. The replacement of most of the world's radio and television receivers, as well as most production, transmission and emission facilities, during the next two decades, as the new technologies are accepted by the public, will support major manufacturing industries. There will clearly be major impact on broadcasters and the broadcasting industry, but those who adapt to and embrace the new technologies will flourish.

Sound broadcasting may be expected to undergo similar far-reaching changes, as digital broadcasting is introduced, both terrestrially and via satellite. There will undoubtedly be a transition period of many years before the new digitally-based services supplant existing FM-VHF services, which themselves took many years to equal the popularity of AM medium-wave sound broadcasting services. Superior quality and wide coverage areas are advantages that these new services may be expected to exploit.

Author

Richard Nickelson is a Senior Counsellor and head of the technical department dealing with the broadcasting-related Study Groups of the CCIR, including the broadcasting-satellite service. He received the B.E.E. in 1959 and an M.S. in electrical engineering in 1961, both from the Georgia Institute of Technology. He has been a satellite communications system engineer since 1963, involved in a number of experimental satellite programs, including *Syncom-2* and *Syncom-3*, *Lincoln Experimental Satellites* and *ATS-6*.

He was a member of the staff of the Lincoln Laboratory of the Massachusetts Institute of Technology (MIT) and participated in the joint design study for the Indian National Satellite *(INSAT)* conducted by MIT and the Indian Space Research Organisation *(ISRO)*. He joined ITU in 1971 as Technical Coordinator for the Satellite Instructional Television Experiment *(SITE)* in Ahmedabad (India). In 1976 he was transferred to Geneva, where he worked as a Project Officer in the ITU Technical Cooperation Department. In 1980, he was assigned as ITU Study Manager for the ITU project on development of rural telecommunications in Africa. He was appointed to his present position in 1981. He is a member of the scientific *Society of the Sigma Xi* and the IEEE *Communications Society*.

The Possibility of Unified Legal Infrastructure on Electronic Information Transfer (Communications in General)

--- covering the both of television broadcast distribution services and visual telecommunications interactive services

Nobuhiko SHIMASAKI
Mitsuo KAJITANI
Susumu SHIRASAWA
NEC Corporation, Tokyo 108-01, Japan

Abstract

Primarily introduced and reviewed is an overall conceptual block diagram of information infrastructures combining telecommunication networks and information service centers such as broadcast program centers. Then two two-dimensional expression maps of information handling service/business alignment are issued from service end-users' standpoint. Presented in connection with them are the description trials on telecommunication service quoting to Maxwell's electromagnetic equations, broadcast service, etc.

Possible unified legal infrastructure composition for electronic information transfer, and possibility of "local and public information alley" deployment are proposed as further study items and discussed, following to a brief review of current telecommunication/broadcast-relevant regulations (centering on Japan's case).

1. Introduction---Information Infrastructures combining Telecommunication Networks and Information Service Centers such as Broadcast Program Centers

Recently a technical possibility (and reality in some countries) of "direct broadcast satellite (DBS) type" end-user receiving service by utilizing TV program distribution via communications satellite (CS) for local broadcast facilities became well accepted. Furthermore attentions are drawn to another technically mature possibility where Optical-Fiber Cable System for B-ISDN end-user access (so-called Fiber-to-the-Home, FTTH/C/P) is commonly applied to the multiple kind of services such as telephone, computer communications, television telephone, and cable television (CATV).

The above two cases are concerned about the combination of (1) "one to very large N (one way)" distribution service of TV broadcast program to many and wide-spread service users, and (2) conventional visual (tele)communications services where audio-visual (including motion picture type) information is transferred in "one-to-n (one way)" mode or in "one-to-one (two way)" mode.

Here a conceptual block diagram of information infrastructure, Fig. 1 (Ref. 1) is introduced as the basis of more balanced observation of the problem from a generic end-user's view point. It can be seen that the above two cases are related to the practical implementation of service users connection subsystem in front of external interface for (transmission and) receiving equipment of service end-user premises.

Table 1 shows, further, the comparison of various "service end-user connection (sub-) systems" in terms of "service mode versus transmission media" combination. These subsystems can be also described in more detail as "Direct Connection (Sub-)System for Public Service End-User Interface". Table 2 summarizes the current concrete implementation modes of principal service end-user subsystems.

Referring to Fig. 1 in association with Tables 1 and 2, it seems obvious that the above-raised technical possibilities (realities) must be understood as the important two possible sophisticated technical triggers, among others, to the rather systematic evolution of traditional discipline of information handling-relevant business operation.

This paper reports relevant preliminary observation results and further study item proposals, based upon a rather end-users standpoint.

They are initiated from the technical side, but extended to service/business alignment. They further reach legal infrastructure reconsideration. They are aiming to pursue the futuristic matching of technical trends and social discipline in IT (Information Technology)-relevant arena, avoiding rather rash thought towards too much simplified "conflict coordination" and so-called "convergence" between broadcast business and telecommunication business.

2. Various Information Handling Service Business Alignment from the Service End-Users' Standpoint

2.1 Free Description Trials on Telecommunication Service, Broadcast Service, etc.

Fig. 2 illustrates the interrelation of the basic information handling services/business including broadcast and telecommunication, expressed in a map of "information handling functions versus media technology varieties". Here, in horizontal axis, five fundamental information handling functions of human society are listed. Three inside-described functions: information transfer, information memory and information processing, withdrawing the remaining two at the both end sides (i.e. presentation and creation), are considered as the fundamental functional elements of information service system in general (Ref. 1). They correspond therefore to the fundamental electronic information handling functionalities of IT (Information Technology) Industry Complex, too (Ref. 2).

In vertical axis, not only electromagnetic/ electronic information media technologies applications but also paper media-utilization and direct human-to-human (face-to-face) contact are listed for reference/comparison.

Referring to this Fig. 2, an IT engineer's free description trials (a basis of definition) of telecommunication and broadcast are shown below. These descriptions are made "naturally" being independent to the historical considerations reflected in the current legal infrastructure on telecommunication and broadcast in many developed countries. They are based upon the standpoint of service end-users, i.e. generally laymen.

(1) Description of Telecommunication

Referring to the horizontal axis of Fig. 2, let us pay attentions to "information transfer" function, i.e., information circulation between information source and destination which are located distantly.

It is proposed to adapt the following as the generic description of (electromagnetic/ electronic) telecommunication:

. "Service function to transfer information in the form of generation and detection at information source and destination respectively, utilizing electromagnetic and/or electronic phenomena in a broad sense which are based upon Maxwell's electromagnetic equations".

It is important that the both of wired communication and radio (wireless) communication are included in the scope of the above description.

Furthermore, the electromagnetic phenomena application for information memory and presentation functions in combination with information transfer are also considered as included in the above scope. This is corresponding to the short and fat rectangular box expression of single-solid line: Telecommunication Service Business.

It is also essential that the information content is kept free from error and distortion in telecommunication. The expression "transparent communication" is utilized to emphasize this requirement. It is further important that information is transferred from right information source to right destination on-demand basis in real time mode (immediately). To do this, the functions of switching, transmission-channel-cross-connect and selection which is to be facilitated in nodes of telecommunication network. Those functions must be combined with fundamental wired/radio transmission (See Transparent Communication Network of Fig. 1).

(Tele)communication (service) business is described as the business to mediate telecommunication among other parties or to provide with telecommunication facilities for communication (information transfer) of other parties. The other parties, i.e. telecommunication service users, in this case, include distinctly not only general service end-users but also information service providers (center-users) (See Fig. 1).

The other parties' information contents are supposed to be not processed nor disturbed nor broken their privacy in telecommunication service business. Here, the principle of communication privacy: "information as the service objective must reach only the receiving side pre-specified by transmitting side" should be assured and guaranteed. This is obviously corresponding to the expansion of a fundamental constitutional right: "freedom of private correspondence exchange" or "freedom of privacy in communication", towards telecommunication services (Ref. 3). The principle is often quoted as "freedom of (tele-)communication" or "privacy of (tele-)communication". This is of course a basis of democracy.

(2) Description of Broadcast

The following sets of information handling functions combination in human social activities are something essential for information-intensified society:-

(a) Gathering, producing (creating) and/or editing/aligning use-worth informations/knowledges systematically and freely, and
(b) Transferring and distribution those

organized information/knowledges, on real time basis or just in time to very large number of people, in the simultaneous and public mode.

Traditional implementation examples of those kinds are journalism (periodicals including newspapers and book-publishing), theater performance and exhibitions.

Broadcast can be interpreted as the combination of the above (a) and also the above (b) in which already above "described" telecommunication functions are utilized. Then the functions of broadcast are divided into two fundamental portions and quoted as:

(a') broadcast program edition
(b') broadcast program distribution.

Here, it is obvious that the principle of "freedom of broadcast" is as important as the principle of "privacy of (tele-)communication" discussed in the above (1) (Ref. 3). The essence of this "freedom of broadcast" is the "freedom of broadcast program edition". In connection with the special telecommunication measures for transparent distribution of edited program (information/knowledges) to be made public, the ordinary freedom of reserving "privacy of telecommunication" is naturally replaced by the "freedom of public information distribution to very large number of service end-users" based upon the free will of information transmission/origination side.

This "freedom of broadcast (program edition)" is obviously corresponding to a fundamental constitutional right: "freedom of press/publication" (Ref. 3).

The business composed of the above (a') broadcast program edition and (b') broadcast program distribution can be called as "broadcast (service) business". However, broadcast business operators, i.e. broadcasters by themselves, do not necessarily produce/edit all the broadcast programs to be distributed, the objective of the above (b'). They by themselves do not necessarily distribute all the broadcast program to be produced, that is, the objective of the above (a').

Quoting to the thin and flat box expression of single solid line in Fig. 2, the fundamentally important and necessary function of broadcast service and broadcast (service) business is to produce, to edit and to store good broadcast programs which are attractive to service end-users. This essential function of broadcast is corresponding to the above (a') and situated at the outside of conventional telecommunication (electronic information transfer) functionality domain discussed in (1).

It is also worth to the emphasis that the function of live direct broadcast program composition is included as the indispensable/necessary portion of the above (a'): broadcast program edition. This subfunction cannot be replaced by any other public media such as electronic memory package media (See Fig. 2).

Historically speaking, the above (b') function: broadcast program distribution was originally implemented in the form of terrestrial radio communication facilities. Later, CATV approach and DBS approach became in service. Now, the possible common utilization of FTTH between telecommunication business and broadcast business is issued (See Fig. 1). All kinds of implementation of (b') functionality are technically overlapped with those of telecommunication business (See Fig. 2). And the particular interesting possibility of converting "overlap" to "integrate" exists in service end-user connection subsystem of Fig. 1.

The separation/combination of the above (a') and (b') in terms of business operation unit making has many alternatives and is regulated differently in different countries. This is a good item of global coordination and alignment in the future.

(3) Other correspondence/comparison of various services

The current interrelationship between telecommunication and broadcast, which are described "naturally" in the above, can be compared with the interrelationship between mail (post)/transportation & delivery service and journalism of paper media type (See two box expressions of double-solid line in Fig. 2). Electronic publishing business of electronic memory package type is also interrelated to mail/transportation & delivery service similarly.

Another correspondence item is seen between (a') broadcast program edition of Broadcast Service Business and the offered information processing/storage portion included in Remote Access Information Service Providing Business (See a dotted-lined box expression in Fig. 2). The presentation of broadcast program center as a kind of information service centers, in Fig. 1 does reflect this natural correspondence.

2.2 Positioning of Motion-Picture-Oriented Services in Another Map of "Transfer Function Features versus Human Interface Media Varieties

Four motion-picture oriented services are mapped in Fig. 3, or another map expression, in which the horizontal axis aligns the feature varieties of information transfer of pure space-wise type as well as of time-wise transfer combined type (Ref. 4). This feature varieties is based upon/modified from B-ISDN Service classification of the CCITT. The vertical axis of Fig. 3 aligns the electronic media form varie-

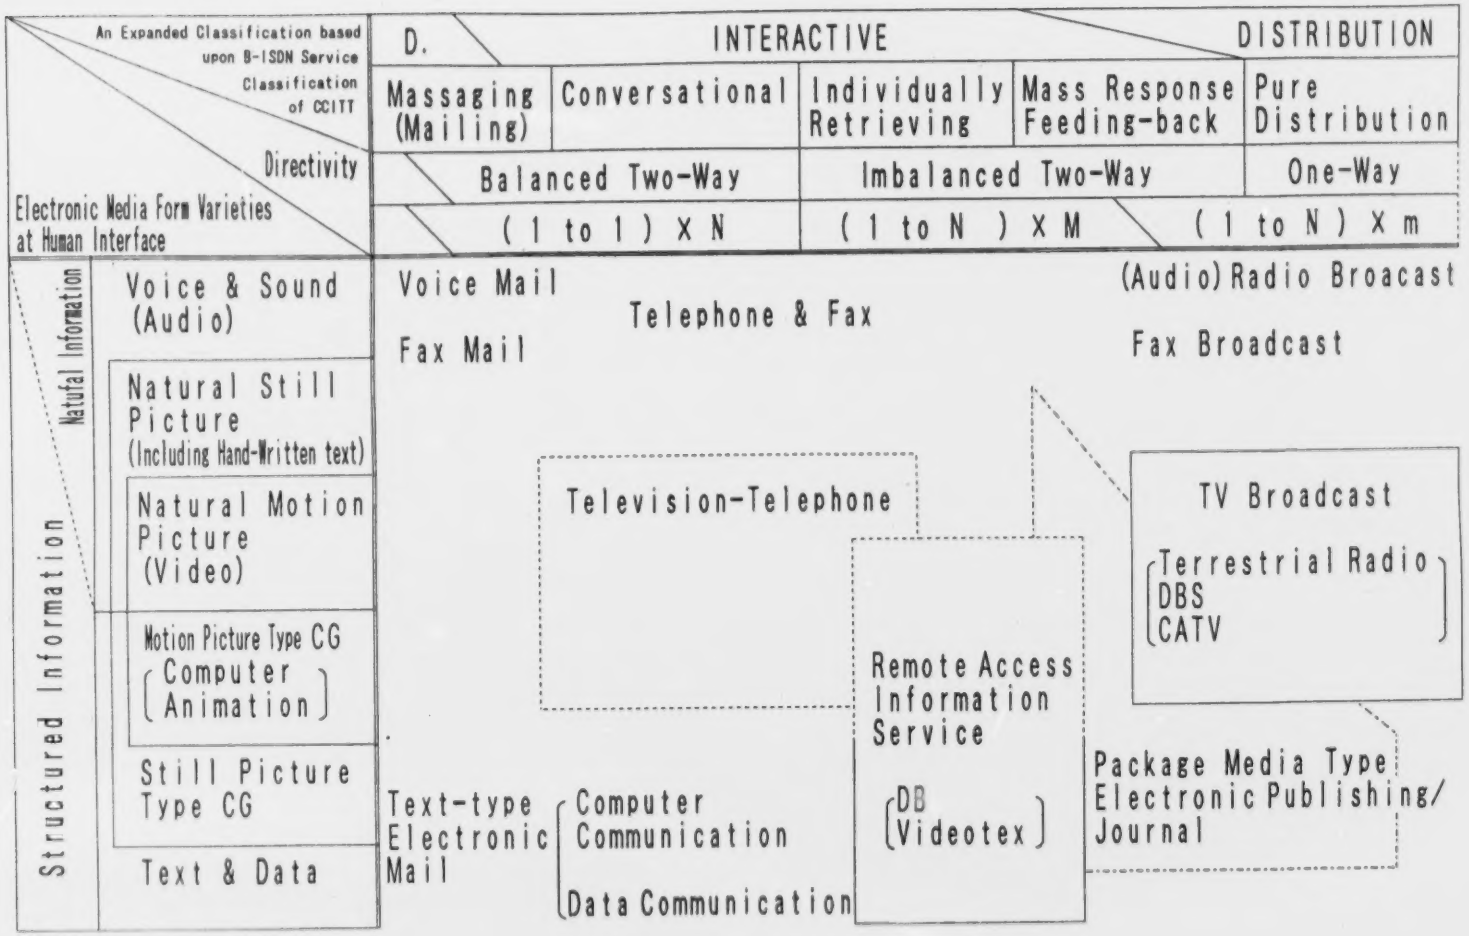

Fig. 3 Positioning of Motion-Picture-Oriented Information Handling Services

ties at human interface of information system/terminal (Refs. 4 and 5), where motion pictures of natural image type and CG type are centered purposely.

Identified four motion-picture-oriented services, which are expressed in "enclosure", are as follows:

(i) TV broadcast
(ii) Package Media Type Electronic Publishing/Journal
(iii) Remote Access Information Provision Service (of futuristic hyper-media type)
(iv) (Futuristic) Television Telephone.

The solid line portion of the "enclosure" represents the reality of the enclosed service, the chained line does the non-electronic transfer, and the broken line portion does the futuristic possibility.

In the map, non-motion-picture-type conventional transfer services are also positioned without enclosure for reference and comparison (Ref. 4).

The detail of discussion on this Figure 3 will be the subject of another future report. But here attentions are drawn only to the prediction that not only the above (i) and (iv), but also (iii) as well as (ii) seem to be important driving factors to promote the motion-picture-type usage of information infrastructure.

3. Legal Infrastructure relevant to Information Handling Services

3.1 Brief Review of Current Telecommunication/Broadcast-relevant Regulations (centering on Japan's case)

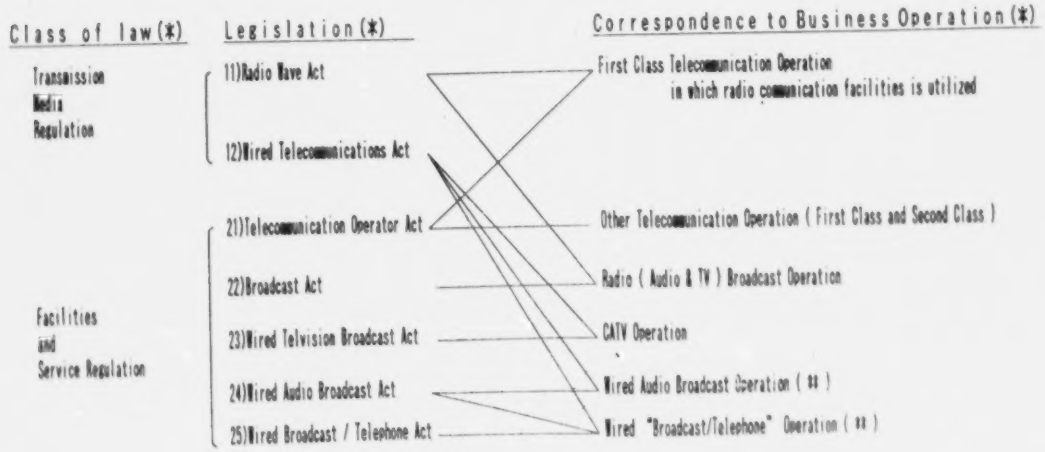
Table 3 indicates the relation of current Telecommunications/Broadcast-relevant Legislation and Business Operation in Japan as an example.

Two acts for transmission media regulation and five acts for facilities/service regulation are applied in various combination to telecommunication operations, radio broadcast operation, CATV operation, etc. Every legal infrastructure including this, reflects of course historical procedure of wired communication, radio communication and broadcast in each country (e.g. Ref. 6).

In the above Japanese legislation system, the following situations are identified as being noteworthy:

i) Radio (tele-)communication, which is the important one of several radio wave applications, and wired telecommunication are specified in fully separated way, in terms of transmission media. (Actually integrated use of transmission media in a system is commonly applied.)

Table 3. Current Japanese Legislation for Telecommunications and Broadcast



Class of law(*)
Legislation(*)
Correspondence to Business Operation(*)
Transmission Media Regulation
Facilities and Service Regulation
11)Radio Wave Act
12)Wired Telecommunications Act
21)Telecommunication Operator Act
22)Broadcast Act
23)Wired Telvision Broadcast Act
24)Wired Audio Broadcast Act
25)Wired Broadcast / Telephone Act
First Class Telecommunication Operation in which radio communication facilities is utilized
Other Telecommunication Operation (First Class and Second Class)
Radio (Audio & TV) Broadcast Operation
CATV Operation
Wired Audio Broadcast Operation (**)
Wired "Broadcast/Telephone" Operation (**)

(*) : English expressions here are arbitrarily translated ones (been not neccessarily authorized).

(**) : Those business operations are not significant in terms of business scale.

BEST COPY AVAILABLE

ii) The technical and business operational possibility of the separation of broadcast program distribution and broadcast program edition is treated rather as an exception.

iii) Specifications on information transfer function for radio and cable-based broadcast operation are separated as exception in Telecommunication Operation Act and rather described on the side of Broadcast Act, Wired Television Act, etc. However, CATV Operation, which is specified as a kind of broadcast operation, is also regulated by Wired Telecommunications Act due to the use of wired transmission channel.

iv) The regulation of CATV conforms to that of radio broadcast in parallel, even though the major basis for radio broadcast operation is primarily the scarcity value of radio wave spectrum in the open space.

In correspondence with the above iv), it is said that other distinct bases of broadcast operation regulation in general can be (a) the discipline of anti-monopoly/oligopoly and (b) the concern on excessive social influence of mass media (especially electronic mass media). Those points seem to be applied, carefully depending upon the service characteristics, the size of business and/or the character of transmission.

3.2 Possible Unified Legal Infrastructure Composition for Electronic Information Transfer

Referring to Sec.1 (Fig. 1) and Sec.2 (Fig. 2 and 3), suggested is the possibility of unified legal infrastructure for electronic information transfer (electrical communication), as follows:

i) To be established first is the fundamental legislation which specifies the general framework of electronic information communication networks infrastructure (Fig. 1).
This infrastructure covers the both of conventional telecommunications and broadcast systems of all kinds:
(a) Simple or serially/parallelly integrated use of wired/radio transmission media,
(b) Various directivity (balanced two-way, imbalanced two-way and one-way) (See Fig. 3),
(c) Combination of connection ((1 to 1)X N, (1 to middle large M)X M, (1 to very large N)X M) (See Fig. 3),
and
(d) Electronic media form varieties at human interface (See Fig. 3).

ii) To be established in parallel is the fundamental legislation to specify the general characteristic of various information service systems.
They include broadcast program production centers and other service centers of electronic information processing/storage function use (See Fig. 1).

iii) To be positioned under the umbrellas of the above i) and ii) are regulation acts for individual electronic information business such as telecommunications operation businesses and broadcast operations businesses of various kinds (See Fig. 2).

In connection with the above i), the establishment of this legislation might be effective to ease the coordination of radio wave usage between radio broadcast and mobile/personal communication.

Further, in connection with the above i), radio wave (i.e. open space electromagnetic wave) application is not limited to information transfer (communication) in a broad sense. The regulation to other application could be an item of separate act or an independent portion of this fundamental legislation.

In connection with the above ii), Remote Access Information Service Business featured by imbalanced two way mode between information service providing centers and multiple number of end users on individual basis ((1 to N)X M), could be categorized as the third type of mass media business (Figs. 2 and 3) which is discriminated from paper-media type mass media business and broadcast business of radio/wired distribution types.

In connection with the combination of the above i) and ii), perhaps the far futuristic target of study could be the establishment of a "super-" unified fundamental legislation covering all kinds of information handling service business, referring to Figs. 2 and 3. This legislation would possibly cover all electronic information services businesses in a broad sense, including the businesses of telecommunication service (network operator service, communication carrier service) and broadcast and "narrow-"cast businesses covering the both functional aspects discussed in the above (a') and (b') in paragraph (2) of Sec. 2.1. This study might touch upon the "flexible" borderline between electronic media and conventional paper media (Fig. 3) eventually.

3.3 Possibilities of Common Deployment and Operation of "Local & Public Information Alley"

It is further suggested to study the idea of possible legal support to carry out commonly the installation, operation & maintenance of service (end-) user connection system (c.f. Fig. 1 and Tables 1 & 2), by a new kind of organization such as public organizations or independent business firms like so-called the zero-th class network operators (Refs.7 and 8). They are to be separated from conventional organizations such as local telephone operators and CATV operators. Those conventional organizations could continue to be responsible to interactive services like television telephone, and to distribution services like television broadcast, respectively (Refs. 9 and 4) in the era of B-ISDN. In the era, FTTH/P/C type service end-user connection system, which could be called as "local and public information alley", would be possibly deployed by the above proposed new kind of organizations.

4. Concluding Remarks

Service users at home and working place will expect appropriate joint services of the both of television broadcast (distribution) type and audio-visual (interactive) telecommunication type. It is expected that this report, attached with study proposals, will be of some use as a stepping stone to the future optimization study of relevant legal infrastructure and facilities infrastructure in this field of overall information handling service businesses.

Acknowledgement

This report is based upon a study activity carried out by the Working Group-B (in August 1990 - March 1991) of Information Communications Service (ICS) Study Committee of the Institute of Electronics, Information and Communication Engineers (IEICE) of Japan (Refs. 10 and 11).

Authors express their heartfelt appreciations to other WG participants (alpherbetical order): Messrs. Kazuyuki Aoki (MPT), Katsuhiko Furuya (Tokyo Electric Power) and Ko-ichi Takeuchi (NTT); Dr. Youzo Utsumi (NHK); Messrs. Hajime Yamada (Oki Electric Ind.) and Kunihiro Yamada (Ricoh), for their cooperations, contributions and discussions. Authors are also thankful to the kind encouragement and thoughtful guidance of the following ICS Study Committee officers: Dr. Ken-ichi Tsukada (Former Chairman, Matsushita Electric (Panasonic), Prof. Sho-ichiro Asano (Current Chairman, National Center for Science Information Systems) and Dr. Yoichi Sakai (Secretary, NTT).

INTRODUCING FIBER OPTICS INTO THE NEW TOWNS OF THE 21ST CENTURY

****

Thomas A. Reiman
Executive Vice President
Live Oak/Sutter Bay
Roseville, CA USA

Fiber optic networks and the availability of broadband capabilities will lead the information services industry into the 21st century. "New Town", mixed use, developments provide the economic and service base necessary for these networks to emerge in the mass market. New Towns provide the forum for telephony, video and information services to co-exist.

As I open my remarks it is important to recognize a number of factors. Primarily these are that anyone associated with the telecommunications and information services industry feels an almost overwhelming call to address and plan for a broadband future in the 21st century. Each of these participants also wonders which applications and what standards will deliver profitability or perhaps better stated - acceptable returns on investment on this broadband infrastructure. The opportunities include video services delivered in higher definition and increased channel capacities to audiences in the American home.

The challenge is finding the market to deliver those services while recognizing the requirements to "redefine the telecommunications business". Although Fiber in the Loop (the entry forum for fiber networks) is driven by precise standards of technology, service, standards and applications, and we very appropriately debate cost and architecture (curb/home etc.), it can be argued that deploying FITL and "finding" the customer base is somewhere between a **challenge**, an **opportunity** and a **responsibility.**

Having had the opportunity to experience the development, cable industry and telephone perspective, there are some factors worth mentioning.

The phone company and the cable industry don't like each other; although they share a common ultimate goal. The development industry is a conservative, debt driven business that seeks a market edge but generally fails to agree on or recognize how to market advanced technologies in "New Towns" and Master Planned Communities.

Although telco and cable often publicly debate their respected positions, often these industries are faced with similar problems. For the cable industry, pay service revenues are down, new build opportunities are down, and money is "unavailable". For the phone company, the vision of broadband is coupled with the cloud of "who are the paying customers". Competition that never before existed is everywhere; long term profitability is in jeopardy.

The real estate development business is perhaps the most volatile of the three. Land values have changed dramatically, lending in the industry is elusive at best, and markets that were hot are cold and cold are hot. The need to define market stability and cost effective infrastructure is a major requirement.

Even with these important issues, it is unreasonable to expect cross industry cooperation and assertive strategic business decisions immediately. It is also unreasonable to anticipate telecommunications serving as a foundational element of a new town without appreciating outside influences such as regulatory, political and business risk. However, political pressure and solidarity in trade associations is one thing. Making money is another. If the economics of broadband works, "build it and they will come."

The first test for each of the three industries is always economic. It is interesting to note that we are hearing more and more about "investment-led economic recovery". Calls for a substantial increase in public infrastructure spending are heard everyday. Public investment could attack the backlog of rotting roads, bridges, subways, runways and environmental projects.

That in-turn, would create new jobs and markets for mostly domestic goods and services and STIMULATE NEW TECHNOLOGIES".

Others have called for tax and regulatory changes that would encourage utilities and telephone companies, to invest their money in modernization of the public network. Instead of allowing US Regulatory constraints to drive telcos to buy up telecom companies abroad, should there not be a renewed interest in investing in a state of the art optical-fiber grid for the U.S?

This optical fiber grid potentially provides the framework for the "intelligent communities" of the 21st century. A necessary definition here is "what is a new community of the 21st century. In the most recent decades, development has been linked to a particular place. There were residential communities separate from business parks; these were by their nature separate from industrial centers. In addition, certain regional locations, worldwide, defined what would work in which specified location. The business and commerce centers of the world is where business had to be. The tranquil mild climate residential regions is where we wanted to live. Today's world of instantaneous, interactive communications places technology at the desktop of any home or business. It brings world class competitive advantages to any location and considers for the first time a quality of life in concert with a quality of professional services.

My talk today will use the emerging New Town of Sutter Bay in the Sacramento Region of California as a case study. This 25,000 acre planned community places two disciplines at the forefront of planning and implementation; transportation and telecommunications. These, at one time diverse industries, are now definitions of each other. Transportation is telecommunications and fiber optic networks are the link between them. Establishing fiber networks in the new towns of the 21st century is a key element in the next century's success of the telephone, cable television and land development industries. The experience of Sutter Bay is a test tube microcosm of planning for these networks and their consumer acceptance.

In addition I will discuss the community of Heathrow in Central Florida, the first all digital ISDN community in America. Together these frame the essential elements to be considered in the deployment of fiber in new towns.

As reported in Business Week earlier this year, the ability to promote and provide fiber in the public network would require liberalizing both depreciation allowances and regulations that currently prohibit local operating phone companies from offering consumer services such as CATV and videotext.

Assuming that I recognize the audience of this conference, I can predict that telco interests here are in agreement with these philosophies. The realistic "other-side" of this discussion, the established CATV industry, has quite successfully attacked potential changes in depreciation allowances and regulations that could pave the "new road" of an optical-fiber grid. These changes, it has been stated might place an unfair advantage in the hands of the telcos perhaps speeding up the inevitable to pave the way for unfair competition, and drive the interests and influences that made the video delivery service what it is today out of the business. Although this can be seen as an American perspective, it shares strong similarities with efforts to create competition in the U.K., Australia and other international locations.

The arguments are real and relentless. Therefore a middle ground - a partnership attitude must be created before anyone wins and perhaps the national economy(s) loses. The interests of the cable industry have not generally been compatible with the interests of telcos. Although spirited competition has served as the hallmark and foundation of American business, the lack of co-operation between these two industries is sprinkled with regulation, litigation, misunderstanding, mistrust and simple lack of logic.

If we find the right cable operators, with the right property, and the fiber in the loop team presents a realistic outside plant alternative - the deals will materialize the path to strategic partnerships will be laid.

The introduction of broadband services in the late 80s and 90s, coupled with the emerging deployment of fiber in the loop portion of the public network has offered the potential of sophisticated services never before offered to the American home.

This introduction, although technically exciting, has however only begun to meet substantial market demand. Although broadband services will provide a wide range of advanced services, it is the delivery of video entertainment that could bring immediate return on investment. With this premise in hand, telco planning has centered on the expansion of fiber in the loop in new builds and in those communities where demographics and expectation of customer demand has been significant.

The President of Pacific Bell, Phil Quigley recently addressed this by questioning "How do you make sure you're amply prepared for anything, and yet over-prepared for nothing?.... It could cost about $900 billion to build the nationwide broadband digital network that most experts now agree this country will need. "

To achieve some form of competitive position, it is necessary to charge ahead in the construction of this network. This "charge" requires partners. Quigley mentioned that "government" is a potential partner (with some caveats) . In his definition of "partner" he describes one who shares the risk and the rewards of a venture. He reminded his audience however that it was the policy of our federal and state jurisdictions that the public will not be a party to the risks of network modernization. "Judge Greene says you can modernize all you like, however the RBOC just can't sell certain services that you'd build a modern network to deliver." The regulatory commissions are all for modernization - but not until you're sure the new capacity will be used immediately.

Whoever the partner might be, there are similar objectives and concerns are described by Quigley, that is "lest we never forget..... that it's other people's money, and they expect a return; " and in most cases a quarterly return. This is the case in the telephone, CATV and real estate development businesses.

To assume that any investment in bandwidth is a sure winner would be wrong. The right way is the hard way: A careful reckoning of the market direction, and an aggressive effort at **stimulating demand.** Video re,resents the most achievable and most "return rich" investment available in a Fiber in the Loop analysis. The typical American spends 61 hours a year on the telephone, but more than 2400 hours in front of the television: a broadband network can deliver both. Where should the natural interest" lie?

FIBER IN THE LOOP TRANSPORT SERVICES

Fiber in the Loop is not simply a technology or transport medium. It is pipeline to the future, the key component to profitability in the 90s and beyond. Although parity between copper and fiber construction has been elusive to date, indications are that the cross over point will be achieved in the early 1990s. Therefore American telcos can look optimistically to cost effective Fiber in the Loop and a ready customer base: or can they?

Fiber In The Local Loop joint opportunities are at best illusive and more realistically unreachable at this time. The reality is that the best design, the best technology, the best construction is today faced with the accepting that telcos and the traditional market leaders in video delivery, CATV operators, don't recognize the need for working together, and the mutual benefits potentially available to each other. In addition, the essential other element, the real estate and the motivated real estate developer is often not included in the strategic planning.

The reasons for the failure to capitalize on the opportunity are many. In relation to the telco/catv issues the reason is perhaps as simple as two competing industries failing to find common ground.

These two industries believe today, more strongly than ever before, that there is no middle ground between telco interests and CATV industry interests. As the battle is waged in the courts and legislative arenas around the country, the potential loser is not even a participant. That loser, the American consumer, is simply a byproduct of the action.

To analyze this includes operational, fiscal and legal issues that have both set the stage for the battle as well as establish the opportunities for a "partnership". The Consent Decree has established specific "albeit current" guidelines which define and limit the role of the RBOCS. To assume an environment inconsistent with these regulations would be to envision a joint opportunity that might never exist. In this regard, today's paper assumes that fiber in the loop services should be offered in a regulated transport arena with key and specific limitations.

Although the more entrepreneurial interests of a Regional Bell Operating Company in the US might conjure up higher and more attractive revenue scenarios, through programming and content control, it is impossible to establish and "sell" a partnership without strictly and specifically defining the respective roles of each partner. Clearly, the CATV industry sees the telco, made up of regulated and non-regulated companies, as a giant with many arms and legs; unable to shed or separate its regulatory limits from its entrepreneurial ventures.

This paper does not describe in detail the non-regulated new business ventures of a telco, rather it presupposes that "Joint Opportunities in FIBER IN THE LOOP" are predicated on opportunities between cable operators and regulated transport companies.

Therefore the joint opportunity today should be the telco providing broadband transport and the CATV operator providing content, marketing, programming and customer service. The then final link is the New Town development providing the real estate, the opportunity for new, not retrofitted infrastructure and the joint marketing.

Basically speaking a joint opportunity takes advantage of parties each doing what they do best. In this case, the above split very precisely uses the strengths of each organization.

Questions that must be routinely asked and debated are "who should the RBOC do business with? This is especially true as it becomes increasingly apparent that no amount of capital can effectively rebuild the urban cores of America. Try as you might to capture the revenue potential of downtown Los Angeles, Chicago or Miami, the reality of costs (both product as well as labor) is that in the near future it will be prohibitive to retrofit.

Even if retrofit were not the choice, the DS3 highway system resident in American RBOC architecture was never constructed to accommodate broadband video service. Therefore, the decision to pursue and "sell" video transport on a "public network" is burdened by the requirement for expensive equipment such as video codex(s) and other expensive add ons not generally required in a dedicated video transport architecture. This might and often causes telco prices to exceed market rates. In addition, these non-tariffed services generally require customer pricing that is not subject to "average tariff" costs and often places the total price burden on facilities that might perhaps be used in later service offerings. As much as an RBOC might wish to advertise the availability of video transport services, they realistically do not have the refined merchandise to give to even the most willing buyer.

Should the RBOC do business with the developer of "New Towns" throughout America? These New Towns have the ability to not only build large scale communities, but to plan for the deployment of infrastructure and the required usage of services through deed restrictive covenants. This presents an attractive feature offering for broadband services. In addition, many developers of large scale "New Towns" are in fact the service providers for video (i.e. the cable operator), again bringing more centralized revenue potential.

Doing business with either a cable operator or a developer is both the only logical path but also the path laid out with the most potential for problems. This is primarily the case because both of these industries do business very differently than the way RBOCs are traditionally educated to pursue opportunities.

Cable and development are debt driven businesses. In most cases, CATV operators and developers have little fluid capital. Although recent clampdowns on lending have curbed the wild financing options of the 80s, it is very difficult to find net worth on a balance sheet of the developer or CATV operator, their networth is primarily the value when they sell. In this cases RBOCs analyses will generally unveil what they define as "a house of cards". This discovery leads the telco into feeling that they are taking all the risk and allowing developers and CATV operators entre into a business - capital investment free; a factor that single handedly hurts most if not all deals open to telco transport.

This issue is answered by the cable operator by the fears of "common carrier", and the potential "balance sheet" loss of the hard asset "the wire". Although value is based on cash flow multiples, common carrier wire could de-value or no-value existing balance sheet assets enjoyed by the existing CATV industry. This issue cannot be ignored and must be evaluated and addressed by those purporting to promote common carrier transport.

This presentation in its detailed overview of Sutter Bay and Heathrow, will explain the environment of common carrier fiber and its impact on the telephone as well as cable operator.

LEGAL AND REGULATORY CONCERNS

Regardless of the business and fiscal desire of a specific telco to introduce FIBER IN THE LOOP and attract network transport customers, there are essential and imposing legal/regulatory hurdles that must be addressed by both telco as well as CATV operator.

In an environment sprinkled in proprietary "mistrust", these hurdles appear to enhance the revenue stream of the transport provider (telco), while limiting the options and profitability of the content provider (CATV operator).

The Communications Act of 1934 (as amended), Section 214, clearly outlines the policies and limits on Extension of Lines; these provisions have remained virtually untouched over the past 50+ years. The language of the Act and its approach to network services might appear routine and non-threatening to telco managers; in comparison is conjures up, to the CATV operator, concerns such as crossing enemy lines with no defense. Why?

Cable Television has thrived in past years as a non-regulated monopoly. This monopoly is defined in the most simplistic of terms, "I own the wire". The CATV industry, faced with high construction costs, with service acceptance at 59% of homes passed, has rarely overbuilt neighboring incumbents. He with the wire controls the neighborhood. Even the most ambitious operator, led to the negotiating table to examine telco transport opportunities, is scared off with the prospect of throwing their business plan open to the scrutiny, review and regulation of the FCC. In addition to the simple overview and regulatory scrutiny, "common carrier" reminds the CATV operator that poor marketing could more easily pave the way to competition; a feared if not paranoic concern. Although it can be argued that "the wire" is the least significant reason a customer might elect to subscribe to cable service, telco transport requires a journey into unchartered waters; a journey all too often left unexplored. The key reasons are really quite simple:

Access: A competitor could demand access to common carrier facilities without the typical investment. After all, service, the only real protection of one's investment has not been a hallmark of the industry.

Timing: An FCC 214 permit can take anywhere from 8 months to 3 years to process.

Three years is often the length of time a cable operator would take to construct, market and then re-sell an entire system.

Scrutiny: A 214 is a public review process. A 214 is a "telco" permit; what sane and aligned CATV operator would enter into such an Agreement? A 214 announces "common carrier" services. A 214 is a lightening rod for public intervention into a private business. A 214, although required, is more of problem than a solution.

THE FINANCIAL COMMUNITY

At $15-$18,000 per mile, building a coaxial or fiber CATV plant is an expensive proposition. This base cost, coupled with inherent difficulties in financing such costs makes cable an expensive business. That expense is however justified in that it stakes out one's territory; it is in fact geographic ownership. In addition, that capitalized investment is a balance sheet investment that is often used in the refinancing and plant extension arrangements that build toward long term profitability. Although the actual plant is void of any relationship between customer service and programming quality, it is in fact a basis for a CATV operator's existence. To this end telco transport, irrespective of its quality and minimal entry fee to the operator, is a questionable commodity that must be explored, defined and justified prior to mass market acceptance as anticipated by telco planners.

In addition to these substantive issues, the cable system resale market as defined by the brokerage community remains a question that must also be addressed. A cable system will often sell every 5-7 years. The sales price, although often defined as a specified cash flow multiple, is computed assuming ownership of plant and plant quality. The resale value of a cable system with no proprietary plant is certainly suspect.

THE LONG TERM TELCO INVESTMENT

Every RBOC currently envisions itself as a long term participant in the video delivery business. Although it is impossible to predict regulatory and legal changes that might allow entry, certain key decisions today could provide a logical path forward regarding new business opportunities into the 21st century. The eventual entry of telcos into the CATV industry might in fact encourage current FIBER IN THE LOOP transport opportunities rather than deter them. The working knowledge of a partnership with the CATV industry might provide valuable long term market experience for both sides. The business of doing business, such as customer service and marketing strategy can be learned in the short term through joint agreements that achieve high returns for both industries; TRUST - FINDING THE RIGHT PARTNER THE KEY.

CONCLUSION

A CHALLENGE, AN OPPORTUNITY AND A RESPONSIBILITY. As addressed in my opening remarks there might very well be a split between these three (3) elements as we investigate the future of broadband services and public network FIBER IN THE LOOP.

Great opportunities in American business often fail to reach their intended and projected objectives. FIBER IN THE LOOP brings broadband technology to the doorstep of the 21st century American home. This talk has tried to build around the very specific objective of insuring a successful future for FIBER IN THE LOOP to both the CATV as well as telco industry.

In addition, it recognizes that the New Towns of the 21st century hold the key to successful implementation. This successful future is tied to a number of very precise and identifiable issues. If broadband fiber is a strategic asset to the telco, then its installation must be aggressively pursued regardless of "break-even customers" being immediately available. This might require shareholder investments to a degree not generally considered. To the cable operator this means that assets and value must be redefined. This redefinition recognizes that the outside plant is not the strategic asset.

To the real estate development industry it is again a redefinition. It is a redefinition of how we build our homes, offices, streets and transportation systems. It captures a strategic market factor and provides the opportunity to "build it in our homes of the 21st century". It recognizes that our children will live and communicate very differently than we do today. It identifies trends in land use and commercial growth and captures information services into the mainstream of our daily and social lives.

This redefinition on the parts of all participants represents the recognition that a competitive era is upon us. We must recognize that answering the call of competition is more of a concern to American business than the potentially selfish issues of "telco versus cable"- the time to come together in a spirit of partnership and co-operation is upon us.

The questions remain, however as to the proper motivation and perspective necessary to ensure that there is a broadband future in front of the service providers that addresses the combined voice, data and video needs of the American consumer. The consumers of the 21st century need your willingness, your desire and your ability to reduce if not eliminate barriers that will bring us the keys to the front doors of the American home - the keys to the revenues and services needed to achieve mass market penetration and mass market acceptance of these services.

The Cable industry is waiting. They are waiting because they have the same economic and revenue problems the phone company has. Those visionary enough to desire advanced services in a "composite information age" will look to the phone company. The development industry is waiting to understand what is going on and how they can adapt to a changing marketplace. The tide is turning; as indicated in recent regulatory changes.

It takes time and a dedicated effort toward finding the right customer at the right time at the right price. If that is accomplished, the partnership opportunities for broadband and information services in the new towns of the 21st century will be viewed as a resounding success.

The Commercialization Of Space

Linda M. Rankin
Telesat Canada
Ottawa, Canada

Abstract

This paper will examine what the business of satellite really is. After 20 years in the business, Telesat has learned that the business is not satellite transmission, but, rather, entertainment, information, and education services. But before this business can work in any domestic environment, there are three fundamental issues which must be understood. The first is that there is no business known as satellite communications; the business is applications, and satellite technology is only a part of a truly effective communications network. The second point to be considered is that the competition for satellite is not the terrestrial transmission networks--it's not fibre. The competition for satellite is found at the application service level. Finally, every satellite company must deal with the issue of regulation. If that company is to survive it must be allowed to earn money, so regulating the technology is no longer the answer because it makes a satellite system less viable than a terrestrial system. In order for satellite companies to operate on a "level playing field" regulation must shift from the technology to the application.

For more than 20 years now Telesat has been developing and operating Canada's domestic satellite service. Telesat ushered in the age of satellite communications when it launched its first Anik satellite in 1972. And earlier this year we launched the largest and most powerful domestic communications satellites ever put into space. That history has made Telesat the world's most experienced domestic satellite company, and its employees have earned an international reputation for engineering expertise.

Since 1985, Telesat has offered a growing portfolio of high-quality voice, data, image and video services that offer Canadian businesses the competitive edge that is so important in today's expanding global marketplace. Those services and others currently in development have transformed Telesat from a transmission service provider to an applications service provider, an experience which has given the company a unique perspective on the satellite communications industry.

Throughout its years of operations, Telesat has never had a loss year, but it has had very few years of reasonable earnings, or of earnings comparable to those routinely achieved by its terrestrial competitors. We believe this experience is not very different from that of other satellite carriers. Very few of the satellite operators around the world who publish financial results have ever been able to achieve adequate earnings for commercial operations.

This being the case, Telesat has often grappled with the issue of what the business of satellite telecommunications really is. After 20 years of launching and managing Canada's domestic satellites, and commercializing Canada's space, Telesat has learned that the business is not simply satellite transmission services, it's telecommunications applications.

We have also learned that isolating the satellite technology from the terminal and telecommunications access technology from the networks is incompatible with business success for the satellite operator. Although some regulatory environments insist on this scenario, the fact remains that a satellite operator must have access to telecommunications traffic on an equal footing with its terrestrial competitors if it is to be commercially viable.

In order to understand this, and in order for the satellite business to work in any domestic environment, there are three fundamental issues which must be understood. The first is that if there is no business known as satellite communications, and the business is really telecommunications applications, then satellite technology is only part of a truly effective communications network. The second point to be considered is that the competition for satellite is not the terrestrial transmission networks. It's not fibre. The competition for satellite is found at the application service level. Finally, every satellite company must deal with the issue of regulation. If a satellite company is to survive it must be allowed to earn money, so regulating the technology is no longer the answer because under that type of regulatory structure a satellite system is less viable than a terrestrial system.

Only by dealing with these issues can a satellite company become successful, and only by dealing with these issues can a satellite system be truly commercialized

The Business Of Satellite

When Telesat first entered the business the idea persisted that the role of satellite in communications was as a bulk communications transmission provider, or carrier. Telesat is now in its third decade of operation as a satellite communications provider, but until a little over five years ago our market was limited to other telecommunications service providers. We were essentially a carrier's carrier, a wholesale provider of bulk telecommunications capacity to other carriers, such as Telecom Canada and Unitel, formerly CNCP. During that period, Telesat depended completely on other carriers to develop and market end-to-end satellite-based communications services which would generate revenues. But although the carriers were willing to use satellite services themselves, they did not promote satellite private network applications for what they saw as a competing technology.

This all changed in 1983 when Telesat took the initiative and began to take its own services to the market. We obtained the right and began offering retail level services to TV broadcasters. In 1985 we gained the right to take the next step, and began developing and marketing business communications services directly to corporate customers. Since that time, we have been providing both broadcasters and businesses with a versatile, reliable, alternative source of communications services.

Our marketing efforts have met with considerable success and today we are the carrier of choice for the broadcast industry. Nearly everything Canadians watch on television is transmitted via our satellites, and every TV network in Canada has switched from terrestrial networks to Telesat's satellite distribution services. That's how most Canadian businesses have known us for some time. But we have also developed reliable, high'-quality, end-to-end communications services to meet the needs of the business community, and many Canadian organizations have already opted for the satellite solution.

One of those customers is Canada's national newspaper, The Globe and Mail. For more than ten years that publication has been using satellite to transmit its national edition to major cities across Canada. Other organizations have also discovered the satellite option. Banque Nationale, Hudson's Bay, Canadian Tire, Gandalf, and the Atmospheric Environment Service are only a few.

What we've learned from all this is that a truly commercial satellite system offers the flexibility, cost-efficiency, and consistency not available from other systems. That's because the very nature of satellite communications makes this possible.

A satellite network offers flexibility because of the relative simplicity of a satellite communications system. Satellite links can be established virtually anywhere quickly and with a minimum of effort, and locations can be added, moved, or upgraded as needs change. A satellite system is flexible enough to allow existing terrestrial locations and equipment to be integrated with a satellite network.

In terms of cost, satellite service is generally more cost-efficient than its terrestrial competition. Advances in technology have brought down the size and cost of satellite earth stations so that satellite communications is now an option for all companies. And with the advent of teleports, earth station costs can be spread among several customers, making satellite communications more economically attractive than the terrestrial counterparts. Also, private satellite networks are inherently more efficient than other networks because a single satellite channel can accommodate voice, data, or video communications between any combination of sites within a network. Finally, satellite communications offers further cost advantages because communications costs are based on distance insensitive prices. In a satellite network it would cost no more to send a data file between two cities in the same time zone than it would to send the same file between two cities in different time zones.

But the inherent flexibility and cost efficiency of satellite communications does not mean that the consistency of service is compromised. The very nature of satellite ensures that each site in a network, no matter how remote, receives the same consistent, high quality digital signal, because it goes up to the satellite from the transmission point and can be sent immediately to any number of sites across the country. And because of the inherent simplicity of a satellite network, there is less that can go wrong.

So what we've learned from our customers over the years is that the business of satellite is not simply bulk transmission services, but rather the business of satellite is entertainment, information and education services. Truly successful commercial satellite operators are not and should not be restricted to operating solely as transmission providers. Truly successful commercial satellite operators offer a unique and flexible communications medium which can be adapted to deliver entertainment to the home, data information to the office, or distance training and learning services to any location within a satellite footprint.

Three Issues To Be Understood

In order for a commercial satellite business to work in any domestic environment, there are three fundamental issues which must be understood.

The first is that if the real business of a commercialized satellite system is applications and services, then satellite technology is only part of a truly effective communications network. The financial or commercial failure of most new satellite companies has been the result of not having recognized this. Telesat has tackled this issue by creating a teleport infrastructure.

Teleports are shared-user facilities, where a number of users share the costs of establishing satellite earth stations. Over the past few years teleports have become important communication centers in major cities around the world. Since the first true teleport opened in New York city in the early 1980s, more than 70 international teleports have been established, and by the time Canada opened its first teleport in 1987 there were already 56 teleports in North America alone.

As Canada's national satellite communications company, Telesat has kept Canada at the forefront of teleport development since it opened its first facility in Toronto. Today, Telesat has five teleports operating in major cities across Canada, with a seventh in development on the west coast, and plans well underway for the expansion of its original Toronto site. Now, under a new agreement with AT&T in the U.S., Telesat will soon provide Canadian customers with access to a new teleport in Milwaukee, Wisconsin.

To date, Telesat has invested more than $20 million in telecommunications equipment for the Toronto teleport, and design plans have been finalized for a $15 million expansion to the original facility. Telesat's philosophy in planning the expansion, and in developing a Canadian teleport network, has been to provide environments where different businesses in the same field can find a certain synergy by working under one roof. Perhaps the best example of how that philosophy works is Téléport de Montréal.

Opened in 1987, the four-storey, 160,000 sq. ft Téléport de Montréal was developed in downtown Montreal with an investment in telecommunications equipment of more than $14 million. Today, the complex houses a mix of radio, television and data producers who make use of each other's services and expertise to conduct their business, and it is a unique consortium of successful engineering and commercial innovation.

There are three licensed broadcasters at the teleport: Météo Média, a weather channel, Le Réseau des Sports, a sports channel, and TV5, a French-language co-venture with Europe, all of which are major users of satellite services. The weather channel actually receives its weather data via satellite, packages it at the teleport, and transmits live, satellite-delivered, video programming 24-hours a day.

The synergy extends to other tenants involved in providing services to the broadcasting industry. LA SETTE does origination and transcoding; PMT Video provides studios and post production; and Pixart is a video producer. Telesat has located a sales office as well as its regional network services staff and a new Direct-to-Home satellite service at the teleport. SOGIC, a Quebec government agency which provides funding for film, video, and communications ventures, is another tenant. Finally, to accommodate very small businesses or start-up companies, an executive office center offers support resources such as reception, secretarial and conference rooms to 10 offices.

All these activities are supported by Telesat's technical center which provides 20 transmit services including no less than 13 full-time television uplinks. Telesat also provides numerous satellite receive services, radio services, and television scrambling services. The synergy at Téléport de Montréal was achieved through the cooperative efforts of the tenants, but it was made possible by the environment that was created at the site, and it is that same type of environment that Telesat has tried to cultivate at its sites in Edmonton, Calgary, Vancouver, and Toronto.

This is just one example of how a commercialized satellite system can work in the business environment. And it also shows that although satellite is the central communications tool, the technology is only part of an effective communications network.

The second point to be considered when developing a truly commercial satellite system is that the competition for satellite is not the terrestrial transmission networks; it's not fibre optic technology. The competition for satellite is found at the application service level, and that's where satellite companies should be concentrating their research and development efforts.

The reason for this is simple. As I noted above, we know that satellite communications offers some distinct advantages over terrestrial communications systems in terms of flexibility, cost, and consistency, but the fact of the matter is that all this is technology. Satellite companies promote the technological advantages of their systems and terrestrial companies counter that by promoting the technological advantages of their networks. It's a constant stream of propaganda that customers and potential customers have to wade through in order to get to what they really want to know. And what a customer really wants to know is what is the service you're offering me to solve my communications problem, and will it work?

In the final analysis a customer doesn't really care whether his information is distributed on terrestrial or satellite systems. What the customer really cares about is that his information is getting through at a reasonable cost, and in the most efficient manner available. Satellite VSAT services, therefore, are competing with terrestrial data services, and not with the fact that one is delivered over satellite and the other over fibre. The transmission medium and its network architecture only define the boundaries within which satellite applications can compete with terrestrial counterparts. So, in order for any company to be successful in the satellite arena it must first recognize that its applications services must be as good, if not better, than the comparable terrestrial application. This translates into high-quality, end-to-end satellite services which deliver value, flexibility, control and full service support. It also means that the satellite service provider must have a complete understanding of the customer's business, and the impact of the satellite service on that business in a technical and functional sense.

Finally, every satellite company developing a commercial satellite system must deal with the issue of regulation. If any commercial venture is to survive it must be allowed to earn money. Commercial satellite networks are no different, but in the current regulatory climate the ability to make money is hampered by regulation which is focused on the technology and not the business. If we agree that the business of satellite is communications applications, then regulating the technology is no longer the answer because it makes a satellite system less viable than a terrestrial system. In order for satellite companies to operate on a "level playing field" regulation must shift from the technology to the application. Competition will result and any commercial satellite company worth its salt will welcome competition.

At Telesat we strongly believe that competition is healthy and will only ensure that we continue to deliver the best value and service to our customers. We also believe that the very nature of commercial satellite systems will allow our application services to effectively compete with terrestrial service offerings.

From Telesat's perspective, this is what the business of a commercial satellite system really is. It is not simply bulk transmission services, but rather entertainment, information, and education services. Truly successful commercial satellite operators are not and should not be restricted to operating solely as transmission providers, since truly successful commercial satellite operators offer a unique and flexible communications medium which can be adapted to deliver entertainment to the home, data information to the office, or distance training and learning services to any location within a satellite footprint.

In order to understand that, and in order for the satellite business to work in any domestic environment, operators must understand that the business of satellite communications is really applications, and its true competition is found at the application service level. At the same time, regulators must understand that if that company is to survive it must be allowed to earn money.

Strategies For Market Entry By International Separate Systems

2. **This paper will analyze the policy of the United States that supports limited satellite competition with the International Telecommunications Satellite Organization ("INTELSAT"). This policy initially met with substantial opposition on grounds that separate systems would creamskim dense routes, cause financial harm to INTELSAT and force lesser developed countries to incur higher service costs. The United States attempted to abate adverse consequences of its policy initiative by prohibiting separate system access to the Public Switched Telephone Network ("PSTN"), requiring long term contractual relations and articulating the expectation that separate systems would innovate rather than compete with INTELSAT for switched services. The paper will identify several types of separate systems with an eye toward assessing whether and how international satellite competition can enhance consumer welfare.**

3. Introduction

Most of the international telecommunications and trade policy initiatives in the United States and other nations result from interest in broader global market access, and the belief that enhanced domestic consumer welfare from deregulation can apply internationally. [1] However, international telecommunications and trade matters simply do not have symmetry with any one nation's domestic policies. Domestic deregulation does not necessarily jibe with the traditional PTT model, or any current liberalization initiative. Furthermore, the multilateral, cooperative nature of international telecommunications and trade policy militates against extrapolation from one nation's view. Accordingly, the pace of international liberalization may lack the speed United States deregulators and entrepreneurs would prefer.

This paper will examine initiatives to promote conditional international satellite competition with an eye toward predicting which types of satellite systems and strategies for market access will succeed. Satellite systems, separate from the INTELSAT and INMARSAT global cooperatives, have embraced different profiles and degrees of visibility as they devise methods to present users with a mix of service innovations and price cuts while avoiding legal and regulatory barriers to market access. At one extreme, an operating system has embraced a provocative, trendsetting posture that has achieved success, but perhaps only because the substantial weight of the United States Government was behind the initiative. Another system, with plans to located numerous satellites in the Pacific Rim, lacks governmental weight, but no shortage of ambition. At the other extreme, a number of systems deliberately seek a low profile in a high volume market. Midway lie regional market players and innovators who seek lucrative niche markets.

3.1 Governmental Philosophy Must Support Satellite Competition

In the United States, the FCC's mandate to serve the public interest increasingly points that agency toward deregulation. Other nations' public interest assessments evidence greater appreciation for a businesslike approach, and more likely consideration of non-government alternatives in narrowly defined, non-essential market niches. But no other nation, with the possible exception of New Zealand, currently believes that private enterprise can singularly make telecommunications facilities, services and equipment markets competitive and supportive of previously articulated social objectives.

Over the course of twenty-five years, the FCC has unbundled telecommunications equipment from service, [2] permitted tariff flexibility and reduced carriers' regulatory duties, [3] and shown increasing reluctance to impose structural requirements for guarding against anticompetitive practices. [4] It has dismantled a variety of regulatory policies that segmented the market into domestic/international, [5] voice/record, [6] satellite/cable, [7] dominant/non-dominant carrier,[8] and gateway/non-gateway factions. [9] But indigenous foreign markets may lack the size and potential for such reliance on open entry and competition. Many of the United States' policy initiatives, if embraced internationally, could result in stranded investment and wasteful duplication of facilities. For example, the United States domestic "open skies" policy [10] promoting market entry by private satellite operators would result in severe overcrowding of the geosynchronous orbital arc. The proliferation of satellites would threaten the ability of the International Telecommunications Union to resolve interference problems, and would support the claims of developing nations that developed countries are locking up too much of a limited and shared global resource.

The profusion of satellites does not necessarily guarantee that the market will absorb all additional transponder capacity without significant price cutting. Should the market not clear out all inventory, then questions exist whether an open skies policy promotes resource and technical efficiency, and whether society benefits from more satellite options that are sparsely loaded. One critic's view of international carrier collusion and anticompetitive practices, is another pundit's observation that international telecommunications policy requires collaboration even to the point of coordinated deployment and use of facilities and services.

Nations have begun to join the United States in supporting private alternatives to incumbent carriers' submarine cable consortia and satellite cooperatives. [11] But the general global view remains that competition between international cable and satellite transmission facilities--so called inter-modal competition--is not so robust as to support competing consortia or joint ventures, or a laissez-faire regulatory attitude toward how carriers should load such facilities with traffic.

The PTAT-1 cable in the North Atlantic[12] and the North Pacific Cable [13] demonstrate that transmission facility alternatives need not result in destructive competition, and price wars that might prevent carriers from providing essential, non-competitive services. Indeed, the very carriers that make up traditional submarine cable investment and operational consortia have acquired capacity in private cable alternatives realizing faster and cheaper circuit restoration options and some facility cost savings as well.

Cost savings, circuit redundancy and enhanced circuit restoration options notwithstanding, many nations refrain from supporting alternative carrier and transmission facility options. New United States carriers, which lack the common carrier status, do not have a regulatory agency's certification that foreign carriers expect. Such private carriers are perceived as lacking the proper bona fides, the commitment to long term service availability, circuit restoration options and reliability. Notwithstanding attractive prices, private carriers like Private Trans-Atlantic Telecommunications System, Inc. had difficulty in attracting carriers to end users until a certificated international carrier subsidiary of US Sprint acquired the company thereby conferring greater credibility and legitimacy.

4. International Satellite Competition

In 1984, a "Presidential Determination" [14] stated that international satellite systems, separate from the INTELSAT cooperative, "are required in the national interest." This one paragraph document set into motion an extensive policy making process and foreign relations campaign to establish a workable blend of procompetitive initiative and adequate safeguards for INTELSAT. On one hand, prevailing political and economic policies as applied to international telecommunications favor extending domestic procompetitive policies, like mandatory underpricing of some services, that have generated consumer and producer benefits. On the other hand, the international telecommunications marketplace involves pervasive government involvement including policies that have the effect of stifling private ventures and market entry.

The International Telecommunications Satellite Organization ("INTELSAT") represents how global cooperation has achieved ubiquitous satellite service at rates reflecting favorable economies of scale. The United States has executed a treaty-level document that requires a degree of forbearance from national satellite initiatives in favor of the cooperative approach. [15] Article XIV of the INTELSAT Agreement, requires Parties to the Agreement, i.e., governments and their Signatories who provide international services, to consult with INTELSAT prior to using or operating a separate satellite system to "ensure technical compatibility of such facilities . . . and to avoid significant economic harm to the global system of INTELSAT." [16]

Notwithstanding, its INTELSAT Agreement obligations, the United States government, through the Executive Branch and the FCC, implemented the Presidential Determination. In a joint "White Paper on New International Satellite Systems," [17] the Departments of Commerce and State articulated how United States international separate systems could operate without harming INTELSAT. The White Paper proposed criteria, which the FCC subsequently incorporated as conditions to licensure, [18] establishing limits on the scope of direct competition with INTELSAT.

The White Paper proposed that United States separate systems must:

1) not interconnect with the public switched telecommunications network in either the United States or any foreign locale;

2) establish long term contracts for the sale or lease of capacity; and

3) secure a foreign operating agreement and complete the INTELSAT consultation process before commencing service.

The FCC's 1985 decision implemented the Executive Branch's recommendations, and started the process for initial confrontation with, and subsequent accommodation by INTELSAT. After authorizing the Pan American Satellite System to provide international satellite service, [19] the FCC had to ensure that the sole United States Signatory to INTELSAT would fairly perform its task as emissary in the consultation process . The Communications Satellite Corporation ("Comsat"), incorporated by an Act of Congress, [20] must serve the public interest as articulated by the United States government, and pursue the best interests of its shareholders.

Prior to the onset of separate systems, Comsat enjoyed a de facto monopoly in international satellite service to and from the United States with the exception of domestic satellites, authorized to provide transborder services taking advantage of the fact that their footprints traverse nearby nations. Because Comsat must comply with official instructions of the United States Government when exercising its twenty-five percent ownership vote in INTELSAT, occasionally it must work against its business interest and that of its shareholders as occurred when instructed by the FCC, State Department and NTIA to push for the favorable consultation of separate systems. Comsat had to lobby its fellow Signatories to act in a manner which sanctions intra-modal competition, i.e., two types of satellite facility competitors. While most Signatories hedge their INTELSAT investment by participating in submarine cable ventures, such inter-modal competition has been deemed

acceptable. The concept of direct satellite competition, however, was difficult to accept.

The FCC licenses Comsat as a "Carrier's Carrier" in effect enabling it to serve as a middleman between INTELSAT and United States international service carriers. As a common carrier, subject to Title II and III of the Communications Act of 1934, in addition to the Communications Satellite Act of 1962, Comsat cannot discriminate or engage in unreasonable practices. Its sole Signatory status requires it to adhere to United States government issued instructions on how to vote and what to say on matters involving the public, as opposed to Comsat's private interest.

By favoring international separate systems, the United States government assumed the task of directing Comsat that its licensee and public interest obligations obligated it to advocate forcefully to the members of INTELSAT the need for a favorable separate system consultation. Prior to Pan American Satellite ("PanAmSat") the first United States separate system up for consultation, INTELSAT had favorably passed on a number of domestic transborder and regional systems. These include dozens of United States domestic satellites providing services to Canada, the Caribbean, Central America and parts of South America. [21] Additionally, INTELSAT had favorably consulted major regional systems operating in Europe, Southeast Asia, India, Brazil, the Middle East and elsewhere.

5. The INTELSAT Consultation Process

The INTELSAT Executive Organ, based in Washington, D.C., provides the cooperative with expert analysis on the extent of separate system technical interference and prospective traffic and revenue diversion. The Executive Organ staff advises the Board of Governors that serves as the cooperative's Board of Directors and is comprised of Signatory representatives from nations with the highest single investment interest and groups of Signatories whose collective investment share qualifies on quantitative or geographical diversity grounds. The Board of Governors then advises the Assembly of Parties that is comprised of government representatives from all nations associated with INTELSAT. The final document issued by the Assembly of Parties to the party proposing the consultation respects national sovereignty and is stylized as a recommendation. Nevertheless, the pursuit of separate system plans in the face of a negative recommendation would violate the spirit of the INTELSAT Agreement, and would likely result in no other nation conferring an operating agreement.

While INTELSAT was initially faced with as many as five large capacity United States separate systems, only PanAmSat and Columbia Communications, using capacity on two NASA tracking and data relay satellites, have become operational. Another separate system with significant financial backing, Orion Satellite Corporation, has received final FCC authorization and plans a satellite launch in 1993. [22] Still, the cooperative has legitimate concerns over its ability to provide ubiquitous satellite service at globally averaged rates. [23] Global averaging means that rates for high volume routes like the United States to Britain generally are priced the same as service on less dense routes like Nigeria to Thailand.

To safeguard its ability to average rates over a large global network and perhaps more parochial concerns about losing its near monopoly, INTELSAT uses a "worst case" analysis of technical and economic harm. This has meant that INTELSAT will attempt to safeguard non-existent, but possible future satellites from interference, through the use of technical criteria far more rigorous than typically used by the ITU's International Frequency Registration Board.

On the economic front, INTELSAT has vigorously objected to a separate system at the same time it alleges that robust traffic demand necessitates additional satellite capacity. Such a dichotomy called into question the legitimacy of the INTELSAT Executive Organ's analysis particularly because it appeared to assume that it would carry any traffic handled by a separate system. In effect, INTELSAT assumes one-for-one traffic diversion, thereby completely ignoring the possibility of market growth and demand stimulation by separate systems. It is quite possible that consumers' demand elasticities and risk tolerance profiles might limit the extent of direct competition between INTELSAT and separate systems. The latter might serve extremely price sensitive users who otherwise might use air couriers or less immediate delivery options in the absence of a one satellite carrier offering significant price reductions.

The INTELSAT Executive Organ's initial findings on PanAmSat, as it had been with other separate systems, pointed to peril and adverse impact. Many nations had expressly articulated their opposition to United States separate systems, despite the fact that they had participated in other separate satellite ventures and their international carriers regularly invested in trans-oceanic cables that in effect compete with INTELSAT and have no consultation obligation. PanAmSat and other United States separate systems threatened to exceed an unofficial 10% revenue diversion figure that serves as INTELSAT's threshold point for separate system economic harm. That figure represents a running total of all previously consulted separate systems, making it increasingly difficult for new systems to pass muster.

However, both PanAmSat and Orion Satellite have achieved favorable consultations with INTELSAT, and the cooperative recently streamlined the consultation process for systems of less than 30 transponders with less than 100 voice-grade circuits that access the public switched network. [24] While initial United States separate systems became the subject of vigorous lobbying by both Comsat and the United States government, as well as the politically savvy leadership in INTELSAT, recent consultations have become more perfunctory and less contentious.

Having itself waged a vicious informational campaign, including advocacy before the United States Congress, the INTELSAT leadership has grown to realize that the United States intends on seeing its separate system policy implemented, even in the face of a negative Assembly of Parties recommendation. INTELSAT was faced with the prospect of a confrontation, or the necessity of having to moderate its economic harm findings. On several prior occasions, INTELSAT has identified ways to avoid findings of economic harm, primarily by deeming INTELSAT not significantly impacted by the services provided by a particular separate system. In the case of United States-Canada transborder service, INTELSAT concluded that domestic satellites would augment existing terrestrial facilities. In the case of Eutelsat, a regional system with service throughout Europe, INTELSAT reduced its preliminary finding of 10% economic harm from that one system to a less than a 1% impact, on a new found recognition that Eutelsat would augment existing terrestrial options. Even where such terrestrial options were at best skimpy, and at worst non-existent, as was the case with Arabsat in the Middle East, INTELSAT displayed political wisdom in opting not to confront.

United States separate systems aiming to serve dense trans-oceanic routes present INTELSAT with a threat that cannot go unchallenged. There is a justifiable concern that a number of United States separate systems can skim the cream of profitable dense routing leaving INTELSAT as the carrier of last resort for less attractive routes, particularly to less developed nations. Even the prospective of such harm and proliferation of satellite options has the effect of presenting foreign policy and national security concerns. The prospect of INTELSAT retaliation through procurement of non-United States satellites and launch vehicles has made the separate system policy all the more risky.

On the other hand, the United States separate system restrictions have rendered fully 80% of INTELSAT services off limits. INTELSAT has been able retain a policy of averaging costs for switched services over all routes without fear of substantial traffic diversion. Separate systems have concentrated on customized, non-switched offerings like video that have experienced quite robust growth. Accordingly, the few United States separate systems, which actually enter the marketplace, can be considered niche players in no position to threaten INTELSAT, impair spectrum or orbital slot management, harm developing nations, threaten national security concerns or hinder the United States balance of trade. The potential for enhanced consumer welfare, service diversity, some downward rate pressure and innovation is too good to pass up merely on a quite unscientific, internal INTELSAT analysis.

6. Rethinking the United States Separate System Policy

Over the course of several years, many nations have associated with the INTELSAT consultations of United States separate systems. Rather than incur any semblance of economic harm, INTELSAT has experienced absolute capacity shortages in the North Atlantic region and has pursued programs to expedite deployment or lease of additional capacity. What was once characterized as a threat to INTELSAT's very survival has become a relatively insignificant matter, resolved in many instances by expedited and streamlined procedures to free the cooperative to attend to more pressing matters. INTELSAT now has become less preoccupied with separate system competition and more involved in the business at hand: arranging for more capacity and deploying it in ways that make it attractive to users with fiber optic cable options.

The fragile peace between INTELSAT and separate systems was challenged in 1991 with the proposal by PanAmSat that the FCC abandon the public switched telephone network access restriction. [25] The vast majority of commenters favored such abandonment, but the Commission initially chose to confer with the Executive Branch before unilaterally acting to change the separate system policy that resulted from inter-agency coordination. The lobbying campaigns and policy debates have returned, and new concerns about national security have been raised on the ability of the intelligence community to monitor all international switched traffic.

7. Types of Separate Systems

7.1 Provocateur/Trendsetter

The Provocateur/Trendsetter model involves a proactive system willing to challenge the status quo even at the risk of creating the perception that it is a threat to PTT revenues and incumbent satellite systems. For any nation's separate system policy to result in actual market entry, at least one satellite system applicant, typically the first or most entrepreneurial, must take an aggressive posture promising users new and cheaper service opportunities. In the domestic United States interexchange telephone market, MCI Telecommunications, Inc. fits the Provocateur/ Trendsetter model, and in the international satellite arena, the label belongs to Pan American Satellite, Inc.

The mere threat of competition forced incumbent carriers like INTELSAT and INMARSAT to embrace a more businesslike approach to service. But at least initially, it fostered a seige mentality that stimulated thinking on ways to thwart and delay market entry. The consultation requirements, International Frequency Registration Board coordination process and regulatory oversight became vehicles to frustrate the Provocateur/Trendsetter. These administrative delays, in conjunction with the fact that the system initially would involve only one in-orbit satellite, works to abate the advantage of early entry and the potential to capture a larger market share than latecomers. On the other hand, real or perceived opposition by incumbent satellite operators and the telephone companies, which must confer operating agreements to accept and hand off traffic, fuels the perception that the Provocateur/Trendsetter is an iconoclast and innovator who must overcome unfair obstacles to serving the public.

The Provocateur/Trendsetter will generate a lot of publicity in its search for a market. But such press coverage will have a mixed message. Depending on the sympathies of reporter and reader, the satellite system will provide the benefits of competition, or create trouble not worth the extra effort users and carriers might have to exert for the privilege to receive and offer service. This type of system appears to savor the battle for initial market access, and later for elimination of any impediment or service barrier, e.g., services that access the public switched telephone network.

7.2 Low Profiler

The Low Profiler model capitalizes on the market development efforts of Provocateur/Trendsetters while deploying additional "plain vanilla" capacity. Carriers of this sort like Columbia Communications, Orion and Unicom seek to ride the coattails of others with an eye toward capturing market share with less expense and travail. They enter the market later, after others have fought policy battles, and secure market share when the risk of PTT retaliation or non-cooperation has abated. What the Low Profiler loses in terms of an untapped market, it presumably gains in the ability to sell or lease capacity with few if any challenges to legitimacy.

Over time, the Low Profiler may have to sacrifice fewer markets and refrain from less "provocative" practices as the concept of separate systems becomes more palatable to PTTs. The Low Profiler can easily lease capacity to users when incumbents face a shortfall or lack the specific type of facility or service desired. And this type of separate system may provide services that access the public switched telephone network without the fallout previously encountered by earlier market entrants. On the other hand, when incumbents have ample capacity and fear lost market share, even the Low Profiler constitutes a competitive threat.

Irrespective of whether it will take away market share from incumbents, the Low Profiler may experience the same difficulties in securing operating agreements with PTTs as the Provocateur/Trendsetter. The marketplace prospects for newcomers are handicapped by consumer perception that it has nothing new to provide. The possibility of a less attractive orbital slot and look angle to the separate system satellite exacerbates this perception.

7.3 Innovator

The Innovator model concentrates on providing greater convenience, flexibility, customer service and access to the rest of the world. Prospective low earth orbiting satellite systems, which promise global or regional mobile telecommunication services via handheld terminals, represent the Innovator model. They primarily addresses consumer requirements rather than make strategic assessments on what profile to assume, and perhaps ignore some of the fundamental requirements like resolving questions on spectrum availability.

The Innovator seeks to provide new services to untapped markets, or to provide better service to underserved areas. Accordingly, it will emphasize the ability to generate new traffic rather than migrate traffic from existing carriers. To the extent the Innovator can serve a rich untapped market, it can exploit inelastic demand and charge supracompetitive rates. But it must predict which market is worth entry and be prepared to frontload substantial investment in the face of uncertainty in terms of consumer demand, spectrum allocations at World Administrative Radio Conferences and spectrum assignment/licensing by national regulatory agencies.

The Innovator expects to reap a hefty profit before other carriers match its innovations. That profit accrues only when the Innovator can attract the first rung of users, so called early adopters, willing to invest in a new terminal and other equipment needed to access the satellite. Where the Innovator proposes the use of a new frequency band, it raises spectrum allocation, regulatory, licensing and policy issues that can convert its status to Provocateur/Trendsetter in short order, particularly if its proposals are perceived as a threat to the status quo and incumbents' frequency assignments.

7.4 Regional Marketer/Niche Player

The Regional Marketer/Niche Player brings new or improved services to a specific region, often simply by employing a better satellite orbital position, beam or signal. Such a carrier can become the INTELSAT for the region or concentrate on market niches, e.g., video and VSATs. A regional market play requires close cooperation of investing national carriers and regulatory authorities. As such, it is more likely that the Regional Marketer/Niche Player will have secured regulatory approval well in advance of launch. Such authorization may come readily in view of the concrete benefits that accrue to the region and the absence of a financial threat to incumbent carriers.

While the Regional Marketer/Niche Player may encourage others to enter the market and provide some degree of price and service competition, the more likely outcome depends on the adequacy of demand, and the response of INTELSAT. In the case of Arabsat, internal management problems and unwillingness to stimulate demand by authorizing diverse video products lead to a less than stellar financial outcome. On the other hand, Palapa, the Indonesian satellite system, has thrived, because of that nation's dispersed island geography, the willingness of other nations in the ASEAN alliance to lease capacity for telecommunications and video service, and the disinclination or inability of INTELSAT to sponsor a region specific discount or improved spot and hemispheric beam to serve the region. AsiaSat has managed to harmonize investors from Hong Kong, China and the United Kingdom while convincing various governments in the region that diversified television options--"television without borders"--will enhance consumer welfare without threatening political stability. Its success may also result from superior signal strength and customer service, despite the higher transaction costs many multinational consumers incur in having to do business with more than one satellite carrier.

7.5 Opportunist/Extortionist

The Opportunist/Extortionist model exploits the International Telecommunications Union procedures on satellite orbital slot registration and the desire of developing nations to become a participant in the satellite delivered information age. The Opportunist simply seeks to capture some of the benefits in satellite technology for its citizens, even if this means cash or free transponders by providing a "flag of convenience" to a foreign satellite carrier. This designation might apply to Tonga's Tongasat and Papua New Guinea's Pacstar as outside entrepreneurs have provided guidance on how these nations might participate in the satellite sweepstakes.

The Extortionist goes several steps further and seeks to broker orbital slot registrations much like one might sell a New York City taxicab authorization or stock market membership. Tongasat registered a total of thirty-one satellites in twenty-six orbital slots before agreeing to narrow its Advance Publication requests with the ITU's International Frequency Registration Board to six. It allegedly sought to "sell" to INTELSAT and others its claim to one or more of these valuable orbital parking places. One can certainly see the intrinsic value in a bona fide orbital slot registration, but the process does not establish a property interest, nor is it contemplated that parties will buy and sell them.

The Opportunist/Extortionist suffers an identity crisis. Is it a legitimate player promising regional service where it is desperately needed? Or is it a front for a foreign entrepreneur seeking to provide a thick route service, or perhaps no service at all? While the possibility exists for better regional service, particularly for developing nations entitled to claim a fair portion of the shared geostationary orbital arc, it is just as likely that the Opportunist/Extortionist has nothing but a paper satellite to pitch. For the latter type of gambit, IFRB procedures will eliminate the registration in six years while INTELSAT and other incumbents have refrained from buying slots they normally can secure for nothing.

1. The FCC believes its procompetitive, open-entry policies will foster "an improved international communications system with more choices for consumers, more diverse service offerings and lower rates." 14. Ronald Reagan, Presidential Determination No. 85-2, 49 Fed Reg. 46,987 (Nov. 28, 1984), implemented in Establishment of Satellite Systems Providing International Communications, 101 FCC 2d 1046 (1985), on recon. 61 Rad. Reg. 2d (P&F) 649 (1986), on recon., 1 FCC Rcd. 439 (1986).

15. Agreement Relating to the International Telecommunications Satellite Organization, done Aug. 20, 1971, 23 U.S.T. 3813, T.I.A.S. No. 7532 [hereinafter cited as INTELSAT Agreement].

16. Id. at Article XIV(d).

17. Senior Interagency Group on International Communication and Information Policy, "A White Paper on New International Satellite Systems," (Feb., 1985)

18. Establishment of Satellite Systems Providing International Communications, 101 FCC 2d 1046 (1985), on recon., 61 Rad. Reg. 2d (P&F) 649 (1986), further recon. 1 FCC Rcd. 429 (1986).

19. Pan American Satellite, Inc., 101 FCC 2d 1318 (1985) (conditional authorization), 2 FCC Rcd. 7011 (1987) (final C-band authorization), 3 FCC Rcd. 677 (1988) (final Ku-band authorization).

20. Communications Satellite Act of 1962, as amended, Pub. L. No. 870624, Sec. 191 et seq., 76 Stat. 419 codified at 47 U.S.C. Sec. 701(a) (1990).

21. Transborder, international services of domestic U.S. satellites required consultation with INTELSAT and addressed many of the economic harm questions raised by separate systems. See Transborder Video Services, 88 FCC 2d 258 (1981); Hughes Communications Galaxy Corp., 6 FCC Rcd. 297 (CCB 1991).

22. Orion Satellite Corp., 101 FCC 2d 1302 (1985) (conditional authorization), 5 FCC Rcd, 4937 (1990) (granting final authority to construct, launch and operate).

23. The INTELSAT Board of Governors did not expressly propose that the Orion Satellite system should be favorably consulted. Instead, it reported to the Assembly of Parties that it had received adequate assurances from the United States and other nations interested in supporting separate system market entry, that they would not oppose efforts on the part of INTELSAT to survive in an increasingly competitive environment. This apparently means that INTELSAT has the implicit approval to deaverage rates selectively to meet competition from separate systems.

24. See,e.g., Pan American Satellite, Mem.Op. Order & Auth, 6 FCC Rcd. 4610 (1991) (granting 100 64 kilobits per second-equivalent circuits for services interconnected with the public switched telephone network between the U.S., Dominican Republic, Eastern European countries not members of INTELSAT, Costa Rica, Bahamas and the United Kingdom); IDB Communications Group, 6 FCC Rcd. 2932 (1991) (use of Intersputnik for services not interconnected with the public switched telephone network).

25. Pan American Satellite Corp., Petition for Rulemaking to Modify Commission Policies Established in CC Docket No. 84-1299 Relating to Separate Satellite Systems, RM-7562 (filed July 18, 1990).

SATELLITE DATA BROADCASTING SYSTEM

Toshiro Mizokuchi,Kochi Yamakawa
FUJITSU LIMITED
Tokyo,Japan

1.Abstract

Fujitsu has developed a point-to-multipoint data broadcasting system that uses communication satellite for domestic use. This is the first product in Japan for a data broadcasting system by satellite communication.
We will go on this development to enhance the services provided by this communication network and advance application development. We are also promoting the development of integrated multimedia satellite broadcasting network systems combined with existing networks.

2.Introduction

In the field of broadcasting business,Nipon housou kyokai (NHK) and Japan Satellite Broadcast corporation (JSB) have started direct television broadcast by using satellite. Because of the reduction of antennas size, the direct broadcast system(DBS) has devloped remarkably. And there are already several million subscribers. At the end of 1991,NHK will begin experimental broadcasts for high-definition TVs.
On the other hand in the field of communication business,Japan Communications Satellite company Inc. (JC-SAT) operates 64 transponders with two satellites. These transponders are used for CATV,satellite TV networks within companies, and other diverse applications. In addition, the following three companies are planning to launch satellites within five years. As the result of these launches the number of transponders will expand to 200.

- Space Communication Corporation (SCC)
- Satellite Japan Corporation (SAJAC)
- Nippon Telegraph and telephone Corporation (NTT)

The technology to use such transponders and the resulting applications will be diversified.

3.Background of Development

(1) Strategic points
One of the largest selling points of satellite communication is the simultaneity of information. Signals sent from a sending station can be received simultaneously at multiple points. Information broadcast systems can effectively utilize this function. (See Figure 1.)
Low speed rate broadcast systems have already been developed. But Fujitsu has developed a high-speed data broadcast system operating at 2 Mbps. It has the following advantages.

①Advantages for users

1:Multimedia information transmission
Various types of data handled by computers can be trasmitted rapidly regardless of the data type (ex. texts,graphics,realistic images and voices).

2:High speed transmission
This system is designed to send data at 2 Mbps rate. This system is hundreds times faster than existing systems.
With this high-speed transmission path of 2 Mdps, information provider (IP) can send a large amount of data (image data,CAD data,etc.) immediately to many points.

3:Economical information transmission
The transmission cost for each receiving stations can be reduced by sending information to multiple points by a single carrier. This means that the transmission cost can be devided by the number of receiving station.

②Advatages for system vendors
One network dose not need full band size of transponder. Each network needs 5MHz bandwidth. If the transponder bandwidth is 27 MHz,4 networks can be buildup.
Transponders can thus be used effectively by sharing the bandwidth.

(2) Technical points
The following require technical development to achive the above-mentioned advantages.

①High reliable transmission
This 2-Mbps transmission system needs 5 MHz bandwidth to achive high reliable transmission path. We adopt the following methods to this system:

- Setting the encoding rate of forward error correction (FEC) to R =1/2
- Binary phase shift keying (BPSK) modulation

This system broadcasts datas from the center

to the receiving stations. There is no returning transmission by satellite links. To improve the quality of the transmission path,highly-reliable error control systems are adopted. Bose-Chauduri-Hocquenghem (BCH) and BEST are performed three times each in addition to FEC.

②Small-sized antenna for receiver

A small-sized antenna with a diameter of 60 cm (standard) can be used because of adopting a triple error correction system.
This system enables a low bit error rate (BER) of 10^{-8} at a high operating ratio (99.9% or higher) even such a small antenna.
Besides,this system adopt a low noise block (LNB) amplifier because of the wide band of 5 MHz.
Since the antenna is small,it can be installed simply and inexpensively. Total communication cost is thus reduced.

③Flexible control of network structure by computers

Data is sent to specified destinations which are managed as a group in the network data base at the center. Receiving stations are registered under each group.
Information in this network data base is distributed to receiving stations via satellite communication lines. When a receiving station receives a broadcast from the center,it extracts only the data addressed to itself based on the received network data base.
The network structure can be changed by modifying this network data base and sending the data base information. These operations can be executed by the center computer. The network can thus be modified flexibly.
Interception of data can be prevented by sending a new cryptographic key at a same time to transmit the network data base. This function enables data security.

4.System Configuration

This system consists of the following center equipment and receiver equipment. (see Figure 2.)

(1)Center equipment

The center equipment receives information from IPs by the terresttrial line and transfers it to satellite links. This equipment consists of the following devices.

①Communication processor

This device is connected to the IP host computer via ISDN (※1) lines. It performs the following processing:
- Packet assignment sent data and conversion to satellite protocol
- Accumulation of packet data
- Management of transmission scheduling

The communication processor can be connected to IPs by the general-purpose protocol of TCP/IP (※2).

※1 ISDN: Integrated Services Digital Network
※2 TCP/IP: Transmission Control Protocol/ Internet Protocol

②Network management processor

This device manages all data bases related to the network (network configuration ,IP information,etc.).

③Sending terminal station

For error correction,this station encodes the data sent from the communication processor. Then,it performes scramble processing and modulation with the BPSK method.
It also provides an interface for directly storing the lines from IPs.

④Earth station

This station converts the transmission from sending terminal station into Ku-band signals of 14 GHz and transmits to the satellite.

(2)Receiver equipment

Receiver equipment receives data from satellite links and send it end terminal such as personal computers.
This equipment consists of the following devices.

⑤Receiving antenna

Antenna receives transmission from the satellite. An offset parabolic antenna with a diameter of 60 cm is used.

⑥Tuner

Tuner demodulates the 1 GHz signals, and extracts data stream of 2 Mdps.

⑦Decorder

Decoder corrects errors with the error correction codes included in the received signals and decodes cryptographic codes. It then extracts the data addressed to this station. And it send the data to the end terminals.
There are two types of interfaces with terminals:
- TTY transmission with RS-232C
- Connectionless trasmission with Ethernet

5. Services Provided by This System

This system provides various services for IP. The services are classified into two types depending on the satellite line use mode:
- Packet transmission
- Transparent transmission

Table 1 outlines the functions.

(1)Broadcast service with packet transmission

The sending center receives data sent with

file transfer from an IP. It performs packet assignment and multiplexes the data with that from other IPs. The broadcast services are then provided through satellite lines. The broadcast services with packet transmission are classified into realtime broadcast service and accumulated broadcast service.

①Realtime broadcast service
Data is sent to the satelite line as soon as it is received form an IP. This service is effective for realtime applications.

②Accumulated broadcast service
Data received from IPs is accumulated. It is sent to the satellite line at the time specified by IP. The accumulation period is from two days before to one hour before. This service is effective for applications which send a large amount of data periodically or those which send the same data repeatedly.

(2)Broadcast service with Transparent transmission
The lines from IPs are directly stored,and the satellite lines divided with time division multiplex (TDM) are provided as transparent transmission paths. The path is provided exclusively as leased line.
The line speed is 64 kbps,192 kbps,384 kbps,or 1.5 Mbps.
This service is effective for transmitting non-accumulated data,such as voice data and compressed moving image data.

6. Target Markets of the Services

One of the targets of this system is to distribute a large amount of data immediately to multiple points at a low cost. To examine practical applications, we evaluated the economical efficiency of this system.

(1)Economical efficiency
In general, using satellites requires a high cost for transmission facilities and transponders. We examined the economical efficiency of the system assuming that ten IPs share a sending center and a transponder.
We assumed a broadcast system with 64-kbps ISDN as the object of comparison. The result is shown in Figure 3. For users who send 1M-byte of data (about ten compressed realistic images) per day,satellite use is more advantageous for 11 or more receiving station. For users who send 5 M-bytes of data (about 50 compressed realistic images),satellite use is more advantageous for 4 or more receiving stations. As a result,using this system is more economically efficient when immediate broadcast is performed to receiving points of over ten stations.

(2)Application fields
As discussed above,this system is suitable for application that require immediate broadcast of large amounts of data. The system may be applicable to the following fields:

①Realtime and emergency Applications
- Distribution of financial information, agricultural products market information ,and technical information
- Online auctions
- Emergency notification (at disaster or accident)

②Applications requiring mass transmission
- Distribution of static image data base
- Distribution of software
- Distribution of voice and music

7. Examples of Applications

This section describes the network application examples for the following aplications:
- Distribution of financial information,which requires realtime transmission
- Distribution of used car auction information ,which requires simultaneity (See Figure 4.)

Stock prices,exchange rates, and futures quotations are changing constantly. It is necessary to distribute such information immediately according to changes. The satellite data broadcast system satisfies the requirements economically.
In auction,the images of desired articles need to be recognized. Graphic images on a personal computer are insufficient for this purpose; higher quality images are needed. A realistic image requires several times as much data as a graphic image. Besides,simultaneity of information distribution is very important even though to send a large amount of high qulity image data with telephone line costs expensive. The satellite data broadcast system solves such problems.
The organizer of an auction gets the data of the cars for sale,as realistic images,from video signals into a personal computer. The data in the personal computer is file-transferred to the satellite center. The center then distributes the data simultaneously to multiple receiving points. If someone wants to bid on a car,the receivers input the data to participate in the auction to the host computer of the organizer,through terrestrial lines.
The price and determination information of the auction is sent via terrestrial lines.
After the auction of a car ends,the information on the next car is distributed through the

satellite link.

8. Conclusion

Because of the advance of digital technology many kind of medias can be treated as digital data. To manage those datas efficiently is becoming important. And data transmission is one of the management.

While about 200 transpondars are going to be operated within five years in Japan, "Satellite data broadcasting system" which handls multimedia is very promising for cultivating markets in new fields. Fujitsu will provide integrated system integration (SI) services from system design to applications.

Table 1 List of service

Classification		Outline Outline of service	IP interface	End terminal interface
Packet transmission	Realtime broadcast	After reciving data sent with file transfer, immediately broadcasts by packet transfer	Physical IF : ISDN 64 Protocol : TCP/IP	Physical IF : RS-232C or Ethernet (10 base 2) Protocol : TTY (for RS-232C) specific protocol (for Ethernet)
	Accumulated broadcaststst	Accumulates the data sent with file file transfer until the specified time. Broadcasts the data by packet transfer at the specified time		
transparent transmission		Provide four type of line (64 kbps, 128 kbps, 386 kbps, and 1.5Mbps) in 2 Mbps satellite line for IPs as leased line	Physical IF : High-speed digital leased line Protocol : non (transparent)	Physical IF : High-speed digital leased line Protocol : non (transparent)

Table 2 Specification of system

Items	Contents
Satellite	Ku-band communication satellite
Frequency	Up link : 14 GHz Down link : 12 GHz
Transmission rate (includes error correction code)	2 Mbps
Modulation method	BPSK
Threshold error rate	10^{-8}
Method of error correction	FEC (R=1/2, K=7) BCH (63 : 56) BEST
Network size	100.000 Receiveing stations for 1 center
Interface	For IP packet transmission : ISDN 64 transparent transmission : High-speed digital line For Terminals packet transmission : RS-232C or Ethernet transparent transmission : High-speed digital line

A Communications Platform for Road Traffic Management

A paper presented to the 1992 Pacific Telecommunications Council Conference

Darryl King, Paul Gale and Maxwell Lay

Australian Telecommunications Corporation and Vicroads, Melbourne, Australia.

This paper outlines work done by Telecom Australia's Corporate Customer Division as part of the scope of the Transport Management Information Systems (TRIMS) agreement between Vic Roads and Telecom.

The paper describes a study undertaken to assess the performance of Vic Roads existing operating systems, analyses the communication requirements of future systems and recommends the selection of a communications platform to meet Vic Roads current and future needs.

1. INTRODUCTION

TELECOM AUSTRALIA

Telecom is the government owned telecommunications carrier which operates in Australia. From January 1992 a privately owned competitor will be able to compete with a new company which will result from the merging of Telecom and the Overseas Telecommunications Commission. The new company will be known as AOTC.

The principal business of Telecom is to supply telecommunications services within Australia and from 1992 Telecom (AOTC) will operate globally.

Some highlights from the 1989/90 year include;

A trading profit of	$1.291	Billion
New capital works	$3	Billion
New optic fibre	182,000	Kms
Revenue	$8.8	Billion

Telecom and OTC are active in international markets with major contracts being awarded in Saudi Arabia Pakistan and Vietnam

ROADS CORPORATION (VIC)

Vic Roads is the State Government Authority which is responsible for the Management of the road network in the state of Victoria as part of the overall transport system. Through this resposibility Vic Roads in association with other government agencies contributes to the social and economic development of Victoria.

Management of the road network includes ; planning, design, construction and maintenance of roads, Registration and licensing of vehicles, licensing of drivers, traffic management and information and road user services.

Key aims are developed in the areas of; Road Safety, Access and Mobility, Economic Development, The environment and Commercial Services.

In 1990 ther were 3 million registered vehicles and 2.7 million licensed drivers.

Some key information follows;

Capital Expenditure	$333	million
Recurrent Expenditure	$343	million
Employees	5,596	
Non Current Assets (inc roads,land,bridges etc)	$8	billion

Vic Roads is active internationally with projects being undertaken in Fiji, Thailand, Indonesia, Singapore, Ireland, New Zealand and Western Samoa.

1.1. Background

Telecom has entered into an agreement with Vic Roads to act as Project Managers and System Integrators on behalf of Vic Roads for the introduction of new technology enabling improvements in the efficiency and effectiveness of road transport.

This agreement, known as Transport Information Management Systems(TRIMS), is for five years (90/91 - 94/95) and the work undertaken in the first year (90/91) will determine project activities to be undertaken in subsequent years.

Part of the scope for the first year entails development of a communications platform to support the systems developed orproposed.

Vic Roads have a vast communications network infrastructure supporting existing operational systems. This network infrastructure is built from a variety of technologies including slow speed telemetry, data , voice and video networks.

With the development of new operational systems, it is now opportune to take advantage of advancements in communications and related technologies and develop a platform to support both existing and proposed systems.

To that end, this study reviews existing telecommunication facilities and defines a strategy plan upon which Vic Roads can design and implement a communications platform to help meet its business objectives.

1.2. General

Although this study was carried out as a joint process between Vic Roads and Telecom, considerable consultation was undertaken with industry specialists, transport user groups, interstate road traffic authorities and public transport authorities as to the requirements that must be met by this platform.

The study considered existing operational systems and in particular concentrated on the performance and cost effectiveness of these systems.

The study also investigated proposed systems Vic Roads wish to implement and has recommended a strategy plan to achieve this.

Special attention was given to both the direction that the international community is taking in developing communication platforms and incorporating standards.

2. STUDY OUTLINE

2.1. Study Objectives

The objective of this study as defined by Vic Roads is to:

"Develop a cost effective, standards based, communications platform providing improved efficiencies that will support existing and proposed operational systems"

2.2. Scope Of Study

The scope of this study is to assess the performance of existing Vic Roads operational systems and analyse the communication requirements of these and future systems to enable a communication platform to be developed to support them.

Recommendations presented address the issues identified in the original Project Management Plan which were:

i. Identify all services currently supporting Vic Roads operational systems together with the costs of these services. The report will assess the performance of the existing platforms.

ii. Investigate Vic Roads existing and future systems in order to understand and specify particular requirements of each system;

iii. Make recommendations for short and long term improvement in the delivery of Vic Roads operational systems including cost benefits;

iv. Define a long term strategy plan for the development of a communications platform supporting both existing and future operational systems.

3. VIC ROADS OBJECTIVES

3.1. Business Objectives

In order to design a communications platform to assist Vic Roads in achieving their business objectives, it is necessary to identify what these objectives are:

Vic Roads Business Objectives have been identified as

- Road Safety

  To achieve a safe road system for the people of Victoria.

- Customer Service

  To provide information, financial and technical services to clients on a commercial basis.

- Road Network Access Management

  To assist the efficient movement of people and freight and to improve access to services for all transport users

- Economic Development

  To assist economic growth by improving the effectiveness and efficiency of the transport system.

- Road System Environmental Enhancement

  To be sensitive to the environment through management of the transport network.

3.2. Functional Objectives

In developing a communication platform it is necessary to identify the broad functional objectives that Vic Roads have in place to achieve their overall business objectives. Consistent with Vic Roads Business Objectives, the wider functional objectives for achieving them have been identified as:

- Provide information to directly influence future land, travel and infrastructure planning decisions. Vic Roads require accurate data on the current performance of the transport network in order to plan and optimise the network to meet the needs of users.

- In planning a trip, allow the decision-maker:

  - to have available all the options by which a trip can be made

  - understand the implications of the potential trip

- Provide the decision-maker with the necessary information required to make an informed decision on how to best meet his transport needs, within imposed restraints.

- In making a trip, make the trip-maker accountable for the cost and other consequences of the trip. Ensure the user limits travel to essential purposes therefore maximising the fficient use of natural resources and minimising theimpact on the environment.

- Provide an infrastructure which:

  - represents an optimum use of community resources
  - protects and enhances the environment
  - operates at maximum achievable efficiency. The transport infrastructure must be cost effective in its operation and management.

. Provide the means to measure and report the performance of the various components of the transport system.

The TRIMS project team is currently developing vehicle management, guidance and information systems to assist Vic Roads in achieving these functional objectives. These systems will provide the mechanism by which Vic Roads will measure the performance of the traffic network, provide a management facility and enable a more efficient use of the network.

It has been agreed that in developing technological solutions to meet the above objectives, a communication platform to support the information capturing and processing systems will be required.

The communications platform will form the common link upon which a number of systems will interface.

3.3. Key Requirements

The following Key Requirements describe the characteristics that Vic Roads require from a communications platform.

. Open Communications

The communication platform must be "open", i.e. provide for the development of any future systems and for the services to be available from a number of suppliers i.e. vendor independent.

. Support Existing Systems

The platform should support or provide a migration path for existing systems. The degree to which this can be achieved will be dependant upon how the existing systems have been implemented.

. Cost Effective

The platform should provide a mechanism to help achieve cost effective business practices. This can be achieved by providing the present communications functionality at less cost or by offering improved functionality for a similar cost.

. Support The "Plug In" System Concept

As Vic Roads will be continually developing and upgrading systems, the platform must enable Vic Roads to implement technology and systems with negligible effect on other users or provide Access To Other Agencies, Businesses and Individuals

Organisations such as the Royal Automobile Club of Victoria(RACV), Public Transport Authority (PTC) and various transport user groups will require access to the systems operated by VicRoads. The communications platform must facilitate and manage the availability of information to agencies, businesses and individuals.

. Network Management

The facility should be available to continuously monitor and manage the platform to ensure the highest level of performance is maintained.

4. EXISTING OPERATIONAL SYSTEMS

4.1. Overview

With Vic Road's formation, a compilation of systems originally designed and implemented by various statutory bodies, i.e.Road Traffic Authority of New South Wales (RTA (NSW)), Melbourne Metropolitan Board of Works (MMBW), now Melboune Water The Road Traffic Authority (RTA), The Road Construction Authority (RCA) and Federal Government, have now been brought together.

These systems were implemented independently and therefore without any strategic direction being adopted for their development or networking.

Consequently there are a large number of systems supported by various technologies and standards, none of which is judged as an appropriate platform for the development of future systems.

4.2. Assessment Of Vic Roads Systems

An investigation into the performance of these systems was undertaken during the course of this study. The conclusions that have been reached are as follows:

i. Basic Technology

These systems were developed to fulfil simple requirements.

With budgetary restraints and simple applications to be met, developers used basic or "bare bones" technology when designing systems. This technology includes simple hardware platforms supported by proprietary protocols.

Further, some of these systems were developed more than 20 years ago with technology that was, in its day, state of the art but now is considered to be rudimentary.

The continued use of these technologies restricts migration of these systems away from existing communication environment to modern, more cost effective solutions.

ii. Standards

The communication protocols used for the existing systems, are generallynot based on international or industry based standards. The systems were largely developed with proprietary protocols, thus limiting migration to more sophisticated technologies.

iii. Scope For Improvement

Although all systems proved to be satisfactory in terms of meeting VicRoads requirements, Vic Roads feel there is scope to improve aspects of The SCATS, the Ericsson freeway phone systems and the Video surveillance(Closed Circuit TV) network. These aspects are:

a. Sydney Coordinated Adaptive Traffic System (SCATS)

Maintenance Costs

Improvement To Algorithm

Utilisation Of Modern Technological Developments

A business case for the redevelopment of SCATS has been prepared by theTRIMS project team and is discussed in detail in the TRIMS business cases report.

b. Ericsson Freeway Phone System

Due to the age and type of technology used in the Ericsson freeway phone system it has become difficult to maintain and will not permit more than one driver to communicate with the control room at any one time. Vic Roads have begun to implement the preferred option i.e. a PABX system.

c. Video Surveillance (CCTV)

Due to the type of technology currently used to support this system, it is not possible to cost effectively implement this network outside theCBD or freeway environments.

v. Cost Effectiveness

The bulk of the communication costs are for SCATS. Vic Roads have optimised the costs for this system by placing the regional computers so that private line costs are minimised.

The remaining costs are for data services, video services and telephone call charges and are minor in relation to the costs for SCATS.

Given the design, type of technology used and the application, there is negligible scope to improve on the cost effectiveness of the these present communications.

Migration to any other type of communication technology would require expensive redevelopment costs which could not be justified by reduction in costs on improvement in performance etc.

5. STANDARDS BASED MODEL

5.1. Open Systems Interconnect (OSI) Communications Model

In designing a communications platform meeting the Key Requirements outlined previously, it is necessary to adopt a communications architecture based on recognised standards.

The Open Systems Interconnect (OSI) model, has been developed by the International Standards Organisation (ISO) as a non proprietary standards based architecture against which organisations can develop communications systems.

Although there are many communication models and architectures available today only the OSI model is recognised as nonproprietary. Communications platforms developed against this model will therefore support all international standards and so the adoption of the OSI model will enable Vic Roads to achieve their key requirements.

5.2. Standards

An "OPEN" communications environment can only be implemented by the adherence to standards to ensure that system components are alike, not only within the system itself but within other comparable systems that are likely to interface to or work with that system.

This fact has been recognised too, by both the European and North American road traffic authorities as they now attempt to develop standards-based traffic management systems similar in function to those that Vic Roads wish to implement.

A standards based platform will meet Vic Roads Key Requirements by providing the following:

- Avoid duplication of equipment and information
- Allow information to be located where it can best be managed, yet enabling access to such information at the point of use
- Avoid restriction to a single equipment suppliers product strategy
- Avoid restriction to a single communication suppliers services
- Allow individual procurement of discrete systems
- Maximise the potential for interworking between separately procured systems, whether within Vic Roads or with users outside Vic Roads
- Simplify future introduction and integration of equipment to meet unforeseen application requirements
- Establish a common technical approach to complement and encourage the realisation of Vic Roads IT strategies
- Achieve genuinely open, and hence more cost effective, communication systems. Enable greater marketing opportunities for systems developed by Vic Roads. Greater exploitation of systems developed on recognised standards can be achieved rather than those developed on proprietary systems.

5.3. Communications Protocol

Before a Communications platform can be recommended it isnecessary to select a communications protocol on which this platform will be based.

The communications protocol will need to:

- Be standards based in order to provide an "OPEN" system and
- Support the communications requirements of Vic Roads future systems.

5.4. OSI Protocols

The Open Systems Interconnect (OSI) defines two network architectures or topologies that can be implemented to support a network over a wide area. These are:

- Dedicated Network (point to point) and
- Packet Switched Data Network (PSDN).

To support these communications architectures, OSI specify communication protocols based on the CCITT Recommendation X.25.

X.25 is a suite of protocols defined between layers 1 and 3 inclusive of the OSI model. This is a stable recommendation and implementations of this protocol are widely available.

5.5. Support For Multipoint Networks

OSI does not presently define standards for multipoint networks. As Vic Roads require a standards based communications platform no consideration has been given to a recommendation based on multipoint networks as any implementation would be proprietary.

5.6. Selection Of A Communications Protocol.

The X.25 suite of communications protocols will be used in the implementation of this platform. This will offer Vic Roads arange of standards-based protocols to support the future systems being developed for this platform. X.25 is also the standard upon which the Australian Government Open Systems Interconnect Profile (GOSIP) is based therefore the adoption of this recommendation will ensure that Vic Roads are compliant with the Federal Governments commitment to OSI.

6. FUTURE OPERATIONAL SYSTEMS

6.1. Overview

In June 1990, a joint Telecom - Vic Roads study was conducted to systematically analyse data to plan, manage and operate the road and traffic system in Victoria.

The emphasis of this work was to identify where new technologies could be cost effectively applied to the capture and management of information about road activity.

As an outcome of this value management study, it was identified that VicRoads needed to implement new data collection and management systems to support the operation of the road network.

These systems included:

- Vehicle Management
- Route Navigation
- Transport User Information Systems
- Vehicle Movement Statistics
- Public Transport Information System
- Radio Data Service (RDS)
- Vehicle Guidance

Currently there are a number of business cases being developed under the scope of the TRIMS agreement addressing these projects.

These business cases include:

Vehicle Tagging Trials

A before and after traffic study for a major freeway project

The business cases define the relationships between the systems and:

i. Strategic model developed as part of TRIMS

ii. Value management study conducted as part of TRIMS

iii. Overseas developments

The business cases will define the scope in terms of objectives of each project.

6.2. Communications Requirements

As the technologies to be used in these systems have not been determined it is not possible to identify specifically what communications requirements need be supported by the communication platform.

Preliminary work completed to date by the TRIMS project team has identified the communication characteristics and technologies that need to be supported by the communications platform.
These are:

i. Support of a large number of dispersed sites (At least 200-300)

ii. Support for low to high data transfer (4KBYTES to700MBYTES/site/day)

iii. Support of both continuous and intermittent (low duty cycle) traffic patterns.

iv. Support CCITT Recommendation X.25 communication protocols

v. Support for CT2 and GSM technologies.

7. MAJOR ISSUES

In order to propose a technically feasible solution it is necessary to identify the major issues that may influence how that solution is implemented.

These issues are actually the difference between the "IDEAL" and the deliverable solution. By identifying these issues, it is possible to design a technically feasible solution and identify what constraints need to be overcome in time, so that the "IDEAL"solution can be achieved.

The following major issues were identified during the course of the study as being most likely to impact on the studies recommendations.

i. Availability Of Technology

the timing for the introduction of new technology may not now allow for the implementation of an ideal solution.

It may be necessary to implement a solution in a phased manner to ensure Vic Roads gets the ideal system in due course.

ii. Cost Effective Solution

Although solutions may be feasible, they may be too expensive to cost justify.

iii. Flexibility In Migrating Existing Systems

Depending on the technical restraints imposed by existing systems, there may be limitations in how quickly these systems can be integrated into the proposed platform.

iv. Availability Of Funds

Availability of funds may influence the implementation of solutions proposed in this study.

8. COMMUNICATIONS PLATFORM OPTIONS

8.1. Options

In meeting the requirements discussed in section 6, three options have been assessed. These are:

i. Utilise The Existing SCATS Private Line Network

ii. Private Packet Switched Network.

iii. Public Packet Switched Network

8.2. Recommended Option

It is recommended that Vic Roads adopt a public ISDN Packet Switched service to support the future operational systems currently being developed.

An ISDN network will offer Vic Roads the following benefits:

- Cost effective packet switched service.
- Standards based network.
- Support for CT2 and GSM technologies.
- Migration path to future communication developments.

Will support the redeveloped SCATS system.

8.3. Costs

As an indication to the cost of implementing a network to support VicRoads future systems, indicative Telecom tariffs have been used. With the deregulation of the communications industry similar services will be available from the second carrier and tariffs may reduce.

i. Remote Site

Each remote site will require an ISDN Basic Rate Access. The ISDN not only provides access to the ISDN public packet service but also support wide band width services e.g. Video Services, CT2/GSM etc. at these sites.

ii. Host Site

The host site will require access to ISDN. Initially a Basic Rate Access will accommodate the expected traffic but in time as the traffic increases this access may need to increase.

Table 8.1 details the costs for a 200 site network.

COSTS

Site	Installation	Ongoing
Remote 200	$122,000	$580,000
Host	$610	$2,900
TOTAL	$122,610	$582,900

TABLE 8.1

8.4. Implementation Strategy

A two stage strategy plan is recommended for the implementation of this communications platform. This plan recognises that the introduction of a communication platform must be achieved over a period of time. It also recognises that there are existing systems for which it would not be cost effective to migrate to a new platform in the short term.

The strategy adopted is designed to best suit the development of VicRoads systems.

It is proposed to install the communications platform to initially support the future systems then, over time, interface existing VicRoads and "Non Vic Roads" systems e.g. PTC, PMA, Trucking companies etc, into the platform, either by specifying interfaces into the platform or by providing gateways.

i Stage 1: Implement Future Systems

This stage will encompass the implementation of the network to support future systems. As these systems are developed and implemented the communication services required to support these systems will be installed.

These services will interface the end systems i.e. roadside devices,detectors and transponders to the central or host computers. and will form the basis upon which the overall communications platform will be developed.

ii. Stage 2: Interface To Other Systems

To enable information to be collected from other Vic Roads systems and also provide access into the TRIMS systems for other transport user groups e.g. PTC, PMA, Trucking companies, RACV etc, it will be necessary to recommend the interfaces necessary for this information transfer.

It is beyond the scope of this paper to define these interfaces in any detail as the systems that this communications platform must support have not yet been developed.

9. RECOMMENDATIONS

9.1. Preparation Of A System Strategy Plan

It was recommended that Vic Roads prepare a strategic plan for the on-going development of existing and future systems.

The strategy plan should address the following:

- Assess the types of systems needed to meet Vic Roads ongoing requirements
- Plan for their introduction including the phasing out of obsolete systems
- Oversee the development and implementation of new systems
- Ensure that new systems are standards based.

9.2. ISDN be implemented to support the following future systems:

- Vehicle Management
- Vehicle Guidance
- Public Transport Information system

ISDN provides:

- A cost effective packet switched service.
- A standards based platform.
- An interface to CT2 and GSM.
- Migration to future communications technologies and standards.
- A platform to support the proposed redeveloped SCATS.

9.3. Existing Systems

i Retain Telemetry Systems On Existing Platform

It is recommended that the existing telemetry systems i.e. incident detection, telemetry (Westgate bridge and pumping stations), weight in motion and traffic statistics systems are maintained on their existing platform i.e. private lines/DDS.

These systems are cost effective with the existing platform meeting the communications requirements of the applications. Migrating present systems to another communications platform would require a complete redesign and both from a performance and financial viewpoint, could not be justified .

ii Replace Existing Ericsson Freeway Phone System.

It is recommended that the Ericsson Freeway phone system be replaced. This system has become unmaintainable. The most cost effective option is the implementation of PABXs to replace the Ericsson concentrators. Implementation of this option has commenced.

In summary the proposed communications platform will begin to be implemented during 1992.

Initially it will be used to carry TRIMS demonstration applications and surveillance video.

As the TRIMS,SCATS and other road user systems are specified then the recommended ISDN based communications platform will be utilised by Vic Roads.

A New Traffic Information Service Delivered over the Cellular Mobile Phone Network

Yukio Ouchi, Seiji Suzaki, Toshio Nishiyama, Masanobu Higashida
NTT Network Information Systems Laboratories
Yokosuka, Japan

ABSTRACT

A new traffic information service delivered over the existing communications media is proposed. In this service, users directly access a traffic information database via the cellular mobile phone network, and get personalized and real-time traffic information through spoken explanations. This is the most important difference between the newly-proposed service and the existing information delivery media like radio broadcast, or audiotex, which delivers general information at predetermined intervals. The new service concept is verified by in-company demonstrations.

1. INTRODUCTION

Heavy traffic jams in metropolitan areas are a serious problem world-wide. In the Tokyo Metropolitan Area, the average driving speed has declined from 13.4 miles per hour (1980) to 9.1 miles per hour (1985). If the public sector could invest unlimited sums in road construction, the problem could be alleviated. However, Japan has a very dense population and land costs are very high. Therefore, road construction in Japan needs large investments and is not cost effective. That is why road construction in Japan has not eliminated or alleviated traffic jams. Although traffic has drastically increased over the last 10 years as show in FIGURE 1, the effective road length in Japan has remained almost the same. This has really aggravated traffic conditions in Japan.

FIGURE 1: Factors Aggravating Traffic Jams in Japan

In such cases information about road conditions becomes extremely valuable, a cost effect system is needed that can supply realtime and personalized information. In many countries in the world, traffic information is delivered through traditional media like radio broadcasts. In several countries, as well as Japan, new traffic information services have been proposed. However, the existing and planned information delivery services are not effective. The proposed system, which fully uses the existing electrical communications infrastructure, can eliminate heavy traffic jams. This paper introduces the prototype of a new traffic information service offered through an existing cellular mobile phone system.

2. THE PROBLEMS OF EXISITING AND PLANED IN FORMATION DELIVERY SERVICES

Our prototype was developed after examining current and planned traffic information delivery services. The details of the services are shown in the references. Such information delivery services are divided into the following three types;

(1) delivery by public broadcast, i.e. TV or radio,
(2) delivery by interaction between a human operator and the user,
(3) delivery by networks and terminals dedicated to traffic information

As shown in TABLE 1, each type of service has its advantages and drawbacks. TABLE 1 summarizes the advantages and drawbacks of each service.

Service Type	Advantage	Drawback
(1) Broad Cast	Cheap Wide-Spread Terminal	Not Real Time Not Personalized
(2) Human Operater	Human - Friendly Understandable Realtime Personalized Wide - Spreaad Terminal	Large Operation Cost Small Capacity
(3) Exclusive Network and Terminal (planned)	Realtime Perconalized Good MMI	Large Inverstment Long Time Preparation

TABLE 1: The Advantages and Drawbacks of Each Known Service

In service (1), the information is delivered through TV or radio broadcasts. It can also be delivered through audiotex and videotex services accessed through the telephone network. In Japan, a multiplex broadcast system overlaying the existing FM system is also planned for traffic information delivery. In these services, it is difficult to deliver personalized information in real-time because only common information can be delivered at predetermined intervals. However information delivery is inexpensive and common existing terminals can be used such as radios and televisions.

Service (2) is supported in Tokyo Metropolitan area. The human operators sit in front of panels that graphically display the current traffic situation. The operators interpret the situation, and deliver the information needed through direct telephone interaction with the caller. The problem of this service is its small capacity and large cost. This service is not efficient and cannot accept a large number of calls, because the productivity of human operators is limited. In addition, the labor costs aggravate the cost-efficiency of this service. Thus, private organizations are effectively locked-out and only public organizations supported by taxes can offer the service. However, it is very flexible and human-friendly because the operators are highly trained and can understand and meet the user's requests and needs by interacting with him. Based on the user's requirements, they can deliver personalized information. The operator can even understand the extent of the caller's geographic knowledge and explain the situation in a way that best fits the caller. The operator not only delivers realtime traffic information but sometimes can forecast the expected changes in the situation and guide the driver to the best route. Since the interactions between the operators and the users are in the form of speech, the traditional telephone network can be used.

Service (3) is now under investigation for future commercialization. There were two traffic information delivery services of this type planned for the Tokyo metropolitan area. The first one was called RACS (Road Automobile Communication System) and had been developed under the guidance of the Ministry of Construction for the delivery of traffic information about the Tokyo Metropolitan Expressway. The second service was called AMTICS (Advanced Mobile Traffic Information And Communication System) and had been developed with the support of the National Police Agency for all roads in the Tokyo area except expressways. The basic concept of these services was similar and they were merged to one integrated system called VICS (Vehicle Information and Communication System) last fall. They use an exclusive communication network and terminals to accept users' demands and deliver information. This demands large investment and long preparation time. These are the major problems of the service. However, this service will be able to deliver personalized and realtime traffic information because the terminals are directly connected to the traffic information center. Since the terminals can be newly designed for this system, a comfortable man-machine interface could be offered.

3. OUR SOLUTION TO THE PROBLEMS

Our prototype service is based on an assessment of the current and planned traffic information delivery services and incorporates the merits of the above services while eliminating their problems.

In Japan, facilities for collecting traffic information like sensors or cameras have already been installed on roads and highways by the public sector. The information collected is transferred in realtime to a traffic information center, processed, and stored in the database.

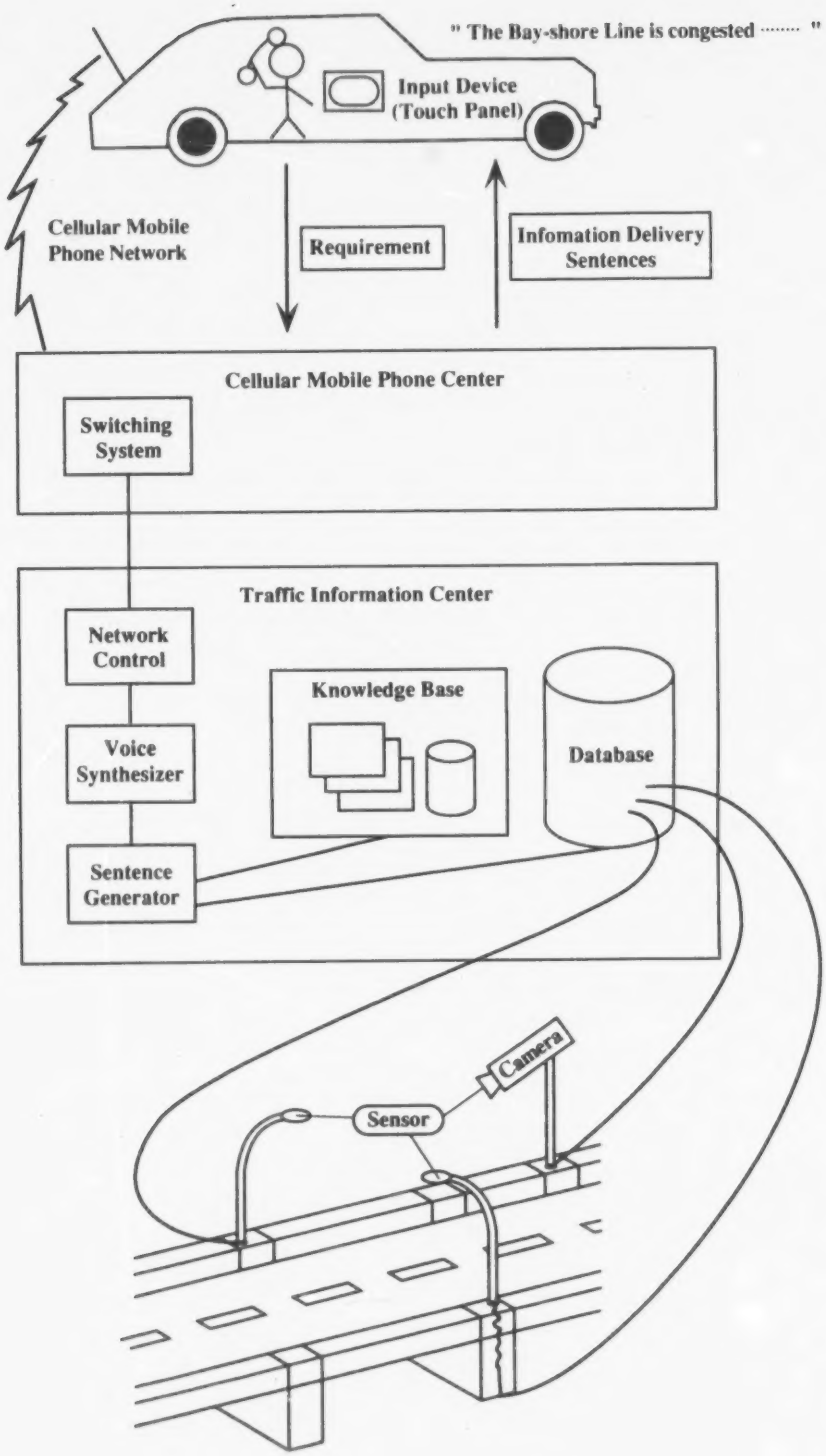

FIGURE 2: The Outline of Our Service

FIGURE 2 outlines the configuration of our service system. It is composed of user terminals (cellular mobile phone, with input capability), and a center machine (virtual database, knowledge base, reasoning module, a sentence generator, a speech synthesizer, and a network controller). The system has not yet incorporated the sensors, the switching and the transmission system, and the network controller. We built a proto-type with the minimum functions necessary to demonstrate the concept and the effectiveness of the service.

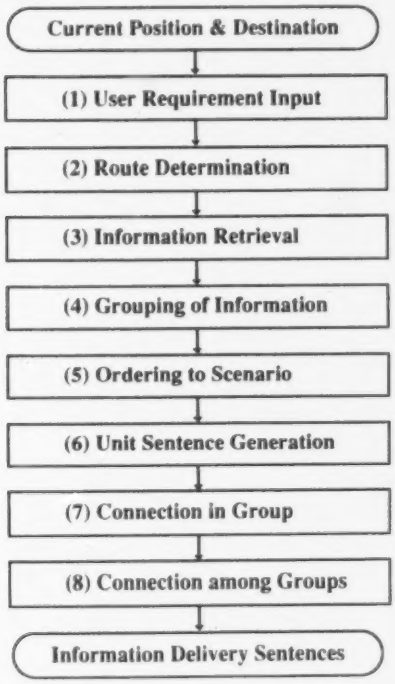

FIGURE 3: The Information Delivery Sentences Generation

In the system, traffic information is delivered following the procedure shown in FIGURE 3. Traffic information is retrieved from the database in the traffic information center and delivered as appropriate. (1) The system accepts the user's current position and destination (FIGURE 4) and (2) determines the shortest route connecting the two points. The knowledge and algorithm for route selection are stored in the knowledge base. (3) It then retrieves the information associated with the route from the traffic information database. Since it retrieves information on demand, users can get the latest information. (4) The pieces of retrieved information are grouped based on the interrelations among them. The interrelation most often identified is the causal relation between an accident and the congestion up to the same point in the same lane. The identification rules are also stored in the knowledge base. (5) The groups of information are ordered along the direction the driver needs to take. The order is the scenario of the information delivery sentences. (6) Each piece of information is converted into a unit sentence and the sentences are grouped following the grouping of information. (7) In each group, the unit sentences are connected following the interrelations identified beforehand. (8) The grouped sentences are finally connected following the scenario. Finally, completed sentences are converted into speech and delivered to the user.

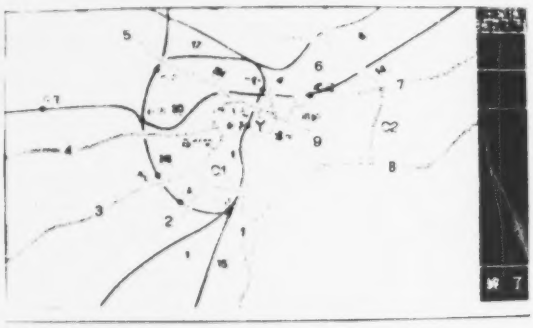

FIGURE 4: A Displayed Map for User Input

Since the information is delivered as speech, users can access traffic information centers through the most widespread communication tool, the telephone and they don't have to purchase new expensive terminals. Since the information is delivered on demand, it is realtime. As shown before, this service can deliver personalized information by retrieving the information on the route the user needs to travel. The automatic service, no human operators are needed for information distribution, drastically decreases the operation cost while offering virtually unlimited capacity. Explanatory sentences are designed to be as human-friendly as the human operators through the employment of modern natural language processing technologies and knowledge processing technologies.
The introduction of this service, which requires comparatively small investment, will ensure the efficient and effective use of the expensive traffic network through traffic redistribution.

4. EXAMPLE OF HOW OUR PROTO-TYPE SYSTEM WORKS

An example of how our proto-type system works is shown below.
Suppose that the database records shown in FIGURE 5 are extracted from the database as the records associated with the selected route.

Rec.ID	Topic	Line	Lane	Start	End	Length
1	Accident	No.3	W-bound	Gaien-RP		
2	Congestion	No.3	W-bound	Gaien-RP	Shinjuku-RP	1.0 miles
3	Maintenance	Loop	Inside	Ginza-RP	Shimbashi-RP	0.5 miles
4	Control	Loop	Inside	Ginza-RP	Shimbashi-RP	0.5 miles
5	Congestion	Loop	Inside	Ginza-RP	Shibakoen-RP	1.5 miles

FIGURE 5: Extracted Records

The interrelated records are then grouped and the interrelations are identified. In this case, records 1 and 2 are grouped into group 1 and identified with causal-relations. Records 3, 4, and 5 are grouped into group 2. The two groups are ordered following the route the driver will take. Thus the final form of extracted information is given in FIGURE 6.

Grp.ID	Rec.ID	Topic	Start	End	Length	Relation
1	1	Accident	Gaien-RP			Cause
	2	Congestion	Gaien-RP	Shinjuku-RP	1.0 miles	Result
2	3	Maintenance	Ginza-RP	Shimbashi-RP	0.5 miles	Cause
	4	Control	Ginza-RP	Shimbashi-RP	0.5 miles	Sub-Cause
	5	Congestion	Ginza-RP	Shibakoen-RP	1.5 miles	Result

FIGURE 6: Final Form of Extracted Information

Each record above is converted into a unit sentence (FIGURE 7).

Rec.ID	Sentence
1	There was an accident at Gaien-RP on the Westbound Lane of the No.3 Line.
2	The West-bound Lane of the No.3 Line is crowed starting from Gaien-RP back toShinjuku-RP for 1.0 mile.
	• • •

FIGURE 7: Unit Sentences

The sentences are connected to each other in a group following the interrelations among them (FIGURE 8).

Rec.ID	Connected Sentence
1 & 2	Because of an accident at Gaien-RP, the West-bound Lane of the No.3 Line is crowded back to Shinjuku-RP for 1.0 mile.

FIGURE 8: Connected Sentence

Finally, the sentences are connected among groups and the final information delivery sentences are given as follows.

"Good morning. Because of an accident at Gaien-RP, the Inside Lane of the Loop Line is congested back to Shinjuku-RP for 1.0 mile. Next, because of the lane control needed for road maintenance at Ginza-RP, the Inside Lane of the Loop Line is crowded for 1.5 miles back to Shibakoen-RP. Please drive safely."
(Original Japanese texts are translated into English for the convenience of explanation.)

5. CONCLUSIONS DRAWN FROM THE IN-COMPANY DEMONSTRATION

The in-company demonstrations last fall confirmed the desirability of the following characteristics;

1. personalized information
2. real-time delivery
3. low cost and large capacity
4. use of widespread access terminals, the telephone

6. FUTURE DEVELOPMENTS

In spite of the many plaudits received by the system during the in-company demonstration, the following 3 points were suggested.

1. The service is too effective. Too many drivers will follow the information provided thus rapidly changing the traffic situation. An algorithm which can forecast the consequences of the information provided and a feedback system that can dynamically change the route folloowing the consequence of the forecast should be developed.
2. New equipment that is easy to operate and compatible with the existing cellular mobile phone system should be developed.
3. Existing voice and natural language synthesis techniques need further improvement.

From now on, we will continue to enhance the prototype system and try to put it into commercial use. We will also try to expand the service fields. The system and its techniques are applicable to weather forecasting, stock market information, etc.. They can also be applied to network operations such as the notification of switching system problems.

ACKNOWLEDGEMENTS

We wish to express our deep appreciation to Dr. Yoichi Sakai for his helpful guidance in this project and to all the members of our research group for detailed comments on the content and style of this paper.

The Airline Industry:
Major Customer and Innovator on the Thin Routes of the Pacific

Daniel C. Smith
AIR Marshall Islands
Majuro, Marshall Islands

1. Abstract

The small airlines of the Pacific and the tourism industry they support need good data communications to compete internationally. The telecom services tend to be expensive and often not readily available. Solutions can be found through new and flexible use of technology and international cooperation.

Despite their size almost all of the small countries of the Pacific have a national airline which requires good data communications to compete internationally. This communication requirement is a significant expense for the airline which is a major telecom customer in its home country. Airlines have the potential to contribute much to the economy but they also can lose substantial sums -- sums which dwarf the income of the PTT. Computer reservations and telecom at AMI runs about 4% of revenue, in line with what other airlines spend. While airlines complain about the costs they have no choice but to pay whatever is required for an effective computer reservations system (CRS). Ordering a reservations circuit in any major city in the world is a simple matter; in the small islands nations of the Pacific it is simple too -- after you have the first system installed.

2. AIR Marshall Islands Network Overview

The AIR Marshall Islands (AMI) data network is diagrammed in Figure 1. Parts of the network are provided by the Societe Internationale de Telecommunications Aeronautiques (SITA) and the rest are varied set of private circuits leased or constructed by AMI.

SITA is the international aviation telecom cooperative. Its global network, a one half billion dollar per year enterprise, is essential to small airlines because it can take traffic from almost any city world-wide. If it is to your advantage to bring your data down in country X then you can do so if you are a SITA member. The main thrust of SITA is that competing airlines join together to meet their communication requirements. In most but not all cases it is less expensive to have SITA transport your data than to lease a private circuit. In the jargon of today, SITA is a provider of virtual private networks for the transactional data, SITA Type A (reservations), and operates several powerful electronic mail systems built originally on telex machines (Type B). (AMI, based on 1990 usage, holds two of the 7,825 shares in SITA. Lufthansa has the most, 390).

SITA also provides essential connections to aviation manufacturers, suppliers, and increasingly, the Transport Related Sector, a diverse group including, for examples, customs offices, tour wholesalers, CRS's., and freight forwarders. All of these are important to the success of an airline.

Most of the Pacific island communication providers are governments or government-owned corporatized organizations--i.e. defacto PTT's. Thus the services and charges are not necessarily determined by the market. This can work to the advantage of the local airline when, for example, favorable tariffs are granted. It works against the airline when there is a lack of flexibility in the services offered or higher than necessary costs.

The health of the travel industry depends in large part on the extent to which the governments and government telecom agencies recognize the need to provide the services the travel industry requires at fair prices. While the PTT's are monopolies the airlines are not and must hold down costs. Air trade agreements usually provide for reciprocity. This means that if my national air carrier can carry passengers to your country, your national carrier can carry passengers to mine.

AMI has had discussions or actual circuit leases in four small island countries and three of them made offers which are substantially better than those received from major metropolitan countries -- including the U.S., Australia, and New Zealand. The small countries need the tourism income and air service and so make concessions to help. Despite the concessions, in all cases the telecom carrier would still have revenue which substantially exceeded costs. Airlines can use their knowledge, contacts, and increased business volume to help reduce costs further. Cost sharing is critical on the thin routes -- thin in terms of both telecom and air traffic.

One of my favorite examples is the little country of Tuvalu (pop. 9,000) 600 nmi. miles north of Fiji both because its policy on data communications is progressive and because success was made possible by contacts made at PTC. As part of the agreement allowing AIR Marshall Islands to use the air trade rights of Tuvalu, AMI was to use its best efforts to install computer reservations. Although the Australian government had given a VISTA earth station to Tuvalu its OTC could not provide any data service at an affordable rate. Furthermore OTC said there was no space segment available. Since INTELSAT was moving a higher capacity satellite to 174 deg. E in 1990 we knew that there was in fact some bandwidth available.

Armed with a letter from the Tuvalu Government we approached INTELSAT which assured us it would make available the space segment if we could find a place to bring it down. After searching the Pacific and finding no country willing to take the other half circuit we said why not use the PACT network equipment in the Majuro earth station. After consulting some knowledgeable people we felt confident our plan would work and the relevant government ministers of the Marshalls and Tuvalu met and the deed was done. We use an off-the-shelf Westinghouse W910 controller to make terminals in Tuvalu look to the CRS like they are in Majuro. Tuvalu has also invited us to find others to share the cost of the circuit. We also want to thank OTC for their assistance after the space segment issue was resolved.

The Marshall Islands also offers some additional examples of flexibility in telecom policy which assists the airlines. The first is access to the spectrum for VHF and UHF links. That is how we get our data to and from the high-tech U.S. missile testing facility at Kwajalein.

The second is easy access to the HF spectrum for voice communications and packet data.

The third is that AMI supplies the systems and data for automating travel agencies. This allows some cost sharing and makes it easier to get our product to the public. There are three competing CRS's delivered to the Marshall Islands so we do not have the luxury of a monopoly.

And fourth, customer premise equipment (CPE) is deregulated.

Although the above activities are grandfathered under the present telecommunications law we continue to push for more flexibility and lower costs in data communications while recognizing that the Marshall Islands National Telecommunication Authority needs some protection from predation on voice. It makes sense for us to look after our data needs and those of related businesses because we have the equipment, training, and expertise to deal with our specialized requirements.

Living in a competitive world ourselves, we would like PTT's to succeed through business acumen and technological wizardry rather than the force of monopoly. We believe that if the PTT's can maintain flexibility and openness to alternative technological solutions, the airlines can devise methods of data distribution that are both effective and affordable. The airlines, together with the banks, form a critical mass for data communication that can make data services affordable for other sectors. We could afford to give communication capacity to educators in the evening for its low marginal cost, for example.

3. Cost Reduction and Control

The major cost of a computer reservations system is telecom. AMI pays only about $30,000 per year for computer reservations but about $270,000 per year in the telecom to support it. With that level of spending is is apparent that we are interested in reducing costs and getting more for our money. The data requirements are modest in terms of volume. What is important is the response in seconds to a reservation request, and the electronic messaging facilities. There are a number of approaches which could produce cost reductions.

3.1 Asymmetric Bandwidth

The flow of data is asymmetric -- the flow outward from the CRS is more than four times that from the remote terminals. This is because very short commands often produce several screens of data.

Thus asymmetric bandwidth would be appropriate -- say 4800 out from the CRS computer and 1200 from the remote terminals toward the CRS. This alone could produce substantial savings. This limited return bandwidth is often easy to find in the satellite channels allocated to telex.

3.2 Use of Standard Protocols

Much of the airline reservations traffic is in protocols which are airline industry specific. For example the P1024B protocol used by AMI is a polling method using six-bit characters and synchronous circuits. This is easy to implement using simple analog bridges but wastes most of the circuit capacity waiting for polling responses with satellite delay.

The airline industry is moving toward X.25 but a useful concurrent move might be to jump directly to a frame relay approach due to the high quality of the circuits these days.

An important benefit of using a standard data protocol is that it can be transmitted by a number of carriers. As long as we run an airline protocol we are locked into SITA except where we can or must rent a private circuit. And while SITA is a responsive service provider, it too is learning to be flexible in the remote islands, and amid world-wide deregulation.

X.25 is a good interim approach because it can be implemented quickly and modern communications processors can be restructured later to new protocols with simple software changes.

X.25 is also attractive because it can be run asynchronously and thus data can be made to fit around voice traffic. It typically takes several seconds to get a response from a reservations computer so a few extra milliseconds delay to fit data around speech would make little difference to reservations terminal users.

How might such a mix of X.25 data and voice be used? In some countries there is a great reluctance to request an additional SCPC satellite voice circuit for dedication to data even if the airlines can afford to pay for the service. In this case the solution is to convert the circuit to data and then with the appropriate commercially - available black box mix data and voice on the circuit. The PTT takes the voice and uses it as it always does and then gives the data to the airline. This solution would be appropriate between Majuro and Ebeye in the Marshall Islands.

At one point we came close to using a VSAT to serve Tuvalu. The major capital cost turned out not to be the earth station but hardware and software to convert the airline protocol to X.25. Direct use of X.25 by CRS's is slow in coming due to existing investment however we expect it from our CRS, Qantam, in 1992 thus making it easier to serve remote locations. (We abandoned the VSAT idea after Tuvalu asked us to figure out a way to use its VISTA earth station.)

X.25 is easy to extend to the farthest parts of the network -- the remote airports having only one or two flights per week. The technology is that adapted from the amateur radio equipment. While AMI has done some successful experiments with packet equipment, it is hard to beat the human operator signal processor who checks in periodically with his SSB radio and picks the reservation request out of the noise. Our more modern, safer aircraft are also more expensive. Just one unnecessary flight avoided or extra one added can pay for the radio for an outer island agent. (For a few dollars more an INMARSAT C terminal would work well also.)

However good our outer island human signal processor is, she cannot afford to sit by the radio all day for part-time pay. Fortunately inexpensive SSB radios and computers can be connected so that short messages can be delivered as hard copy. Getting through reliably on HF is usually a matter of picking the right frequency for the time of day. A modest personal computer is well suited to managing such tasks. Small hotels and resorts on the outer islands can also be tied into global reservations through X.25 connections. The airline will help because travelers need places to stay.

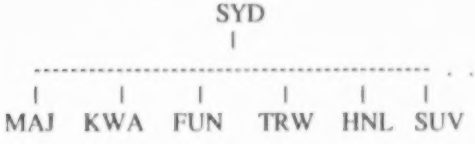
We intend to add X.25 data along side our P1024B data so as to provide new services we presently lack including credit card verification, exchange of interairline agreements and documents, cargo management, and access to aircraft parts and maintenance databases.

Some airlines such as Solomon Airlines have used dialup connections for traditional computer

reservations but the cost per minute was high and the CRS did not want to provide storage for the messages that accumulate while there was no connection.

4. Data Broadcast

A point to multi-point system featuring more efficient use of space segment capacity could be set up without any immediate change of protocols, although change of protocols is inevitable. In the simplest scheme, data could be broadcast from Sydney on one SCPC channel and received at six points. Instead of requiring 12 SCPC space segments the following network would require only seven -- one outbound and six returns. Of course the six returns need not have very large bandwidth. They would not need a full voice band SCPC circuit and could take diverse routings. In the future a TDMA approach might be used for return links.



Broadcast from a hub with varied return circuits.

This broadcasting of data from the CRS host should be done using efficient digital methods which are available off-the-shelf. As usual there is good reason for airlines to share capacity for distribution. The large bandwidth could also be used during relatively idle periods such as the middle of the night to transmit` databases or maintenance manual revisions.

While airline data is unencrypted now some modest encryption might be wise if large amounts of data from many airlines were being broadcast.

Point to multi-point tariffs do not break new ground. We would also like to note that INTELSAT is a hero for us who inhabit the hole in the middle of the Pacific between the hemispherical and/or regional offerings of INTELSAT and others. INTELSAT global beams are all that is available on many of the thin routes and we want to stress, reasonably priced. It is the markups of the telecom carriers that some times make bandwidth unaffordable. We expect future INTELSAT offerings in the central Pacific to open more opportunities.

5. Facilitation of Innovation

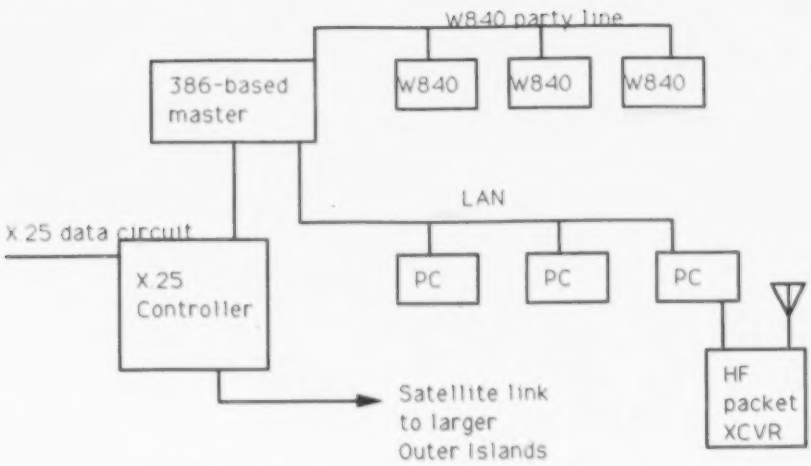
Often the airline industry can propose conceptual approaches but the small PTT's have no place to turn for validation or modest amounts of engineering so as to act on our requests. Also for those PTT's that may be listening, the airline industry does not always know all the answers but is certainly willing to engage in constructive dialog along the lines of, "How can we make this work." International telecom organizations such as the Forum and SITA can provide the contacts and solutions to our problems which are big in island terms but get lost in the noise of data requirements in metropolitan countries. As members of SITA airlines can influence its priorities.

Government to government discussions are critical in many cases. It is easy to find a technical solution if the governments have agreed on an appropriate policy. For example we perceive that the Australian government policy is to promote digital circuits -- despite their giving analog earth stations in their international aid program. All that is needed in many cases to go digital is to change the modem or tap into the digital interface of the existing modem thereby earn a digital tariff. Would airlines pay the capital cost? Surely. The payback period is well under a year. The missing link now is for island governments to raise the issue in the appropriate meetings. To be effective however international experts must know what equipment is actually installed.

In our experience many equipment vendors are eager to help solve interesting problems even though the sale is small. However in the case of large companies it can take a lot of work to find the right person.

'Digital VISTA' is a concept we would like to see implemented because it will bring affordable and reliable data communication with the outer islands. Solutions are readily available commercially as can be confirmed with several vendors regularly present at PTC.

The PC computer revolution makes it easy to change protocols and user software. Whereas before everything was dedicated -- terminals, circuits, modems, mainframes -- today arrangements can be changed frequently. Equipment costs continue to decline and this makes new solutions affordable. With a good 386 PC as a base changing protocols may only involve $500 worth of new software or at worst a couple of



NEXT GENERATION AMI RESERVATIONS OFFICE

Figure 2

thousand dollars for new communications processor board and software.

We do not anticipate buying many more dedicated reservations terminals. In 1992 the computer and communications facilities of our offices will be reorganized along the lines shown in Figure 2. Notice that both a LAN and a W840 party line are driven by a PC.

A year and a half ago it was cheaper to route our data via the long route from Kwajalein to Honolulu to Los Angeles to Sydney. In 1992 some other arrangement may be more cost effective. If I want a new arrangement to get data from Honolulu to Sydney all I need do is pick up the telephone, get a few quotes and make a decision. In the remote islands the project often is more complicated as it involves everybody from international organizations, to national governments, to the person stringing the wire for the last mile.

6. Conclusion

The thin routes of the Pacific require flexible approaches to provision of airline and tourism data services. Because the projects are small they necessarily must take timely advantage of available resources and opportunities to remain affordable and help make airlines commercially viable.

If the airlines are seen to be pushy from time to time it is because they spend a lot of money on telecommunications and financial success depends on the quality of their data networks. On the plus side airline data networks are of sufficient size that they open data opportunities to communities in their markets.

TOURISM IN A GLOBAL CONTEXT: THE CASE OF FREQUENT TRAVELER PROGRAMS

Hamid Mowlana and Ginger Smith

International Communication Program
School of International Service
The American University
Washington, D.C. 20016
U.S.A.

International tourism integrates itself into the complex world of contemporary global affairs through its dependence on telecommunications technologies and its tolerance for widely fluctuating political, economic, and social conditions. A little explored area which illustrates the relationship of telecommunications and tourism in terms of factors of globalization is the frequent traveler program concept.

Introduction

The world's infrastructure has been transformed radically over the last 30 years largely as a result of political, geo-physical, and technological developments. As a result, modern international relations have become characterized by a number of new participants, institutions, and issues beyond that of the conventional nation-state system. A subject area which illustrates well the integration and complexity of contemporary affairs is international tourism and its 1980s creation of the frequent traveler program concept. Although the nation state plays a primary role in the process, participants such as transnational firms are contributing both directly and indirectly to the creation of new institutions in the form of nongovernmental organizations and their activities. This generation of new issues is rendering the fields of international relations and international communication much more complex and their theories more diverse than ever before.

Tremendous changes in communication technologies and transportation over the last two decades have catapulted tourism into political, economic, financial, and cultural prominence as one of the world's most powerful agents in global economic development. In a certain sense, no international interaction is more at home than international tourism in today's globalizing world characterized by continuous and rapid change. The complex relationships between modern financial, technological, and information communication sectors are embodied in tourism, an industry designed to tolerate widely fluctuating political, economic, social, and ecological conditions. That the world has changed is apparent when orthodox economic and political models no longer are or are only partially operative. For example, it has become increasingly difficult to analyze international relations in the area of trade in services without incorporating into the equation such factors as international tourism, modes of international transportation, and flows of technological and financial data.

In the past, tourism was considered -- largely by those outside the field -- as a provincial, peripheral area of domestic and regional studies dealing primarily with commercial and business analyses and applications. Today, however, the multibillion dollar international trade in tourism and travel-related services has created an important sector of economic and cultural activity. Furthermore, the integration of communication technologies into the tourism industry is involving tourism in the politically charged areas of technology transfer and international trade in services, central areas of international political debate for the 1990s and 21st century. In this light, international tourism provides a unique laboratory for social science research.

As a form of international interaction, tourism integrates itself into the complex world of global economic and trade relations. As this occurs, the dependencies as well as interdependencies of tourism vis a vis other economic and financial sectors become more pronounced. Over the last ten years, there has been a direct relationship between international conflict, such as regional war, terrorism, and violence, and the level of instability of the international tourism market. No where was this better illustrated than in the recent Persian Gulf War where the international dimensions of conflict not only affected the flow of tourism worldwide but also demonstrated the close connections between financial, telecommunications, transportation, and accommodation firms and sectors.

The call today from within the U.S. tourism industry, and increasingly from outside, is for tourism to be recognized as a political imperative in the national interest -- economically, politically, technologically, and culturally. It can no longer be treated in economic isolation as a simple question of hardware, of who builds what building of who owns what air or ground transportation, hotel, 747 jumbo jet, or communication network. Growing emphasis on the software or human dimension, such as management, education, labor,

marketing, services, banking and credit, advertising and insurance, are blurring the boundaries between public and private, government and nongovernment, national and transnational interactions.

Similarly, the diminishing nature of the Cold War and the increased mobility of people and information across national boundaries, have created new dimensions of international relations and international communication. These new dimensions are highly complex and are interwoven with the old elements of governments and international organizations. Tourism is comprised of relationships among individuals, small businesses, national governments, and multinational enterprises which not only own the physical hardware superstructure but also now control access to and distribution of the tourism software infrastructure that shapes individual tourists' minds in terms of destinations. These entities are influencing interactions globally between governments, international organizations, and tourism policy fora, setting new theoretical agendas for contemporary international relations.

Tourism as International Relations

Elsewhere we have outlined a model for policy and research (see figure 1) in the form of an integrative model of tourism as international relations.(1) Figure 1 posits the international tourism infrastructure as a central hub in the interaction among issue areas and institutions comprising the international relations policy field.(2) This article focuses on the travel industry's competition over the last decade for the attention of the frequent business traveler, particularly the frequent flyer. It also examines the implications of industry-wide innovation, consolidation, and diversification for international relations.

Figure 2 illustrates the complex relationships between production and distribution, technological and human dimensions of the tourism infrastructure. The model delineates specific tourism items, such as frequent traveler programs, as tangible and intangible sources of power in a globalizing political and economic system. What is important in both models is the emergence of telecommunications technologies as the energy source holding the tourism infrastructure together as a system and stimulating its growth. Communication technologies offer the means for the formation and operation of many new transnational organizations and international institutions.

Frequent Traveler Programs

1. Frequent Travelers - International Tourism Consumers

International tourism has become a complex global process in the high speed movement and management of data and capital as well as of literally millions of world citizenry. The tourism consumer embodiment of this phenomenon is the frequent business traveler, more specifically the frequent flyer. It has become extremely difficult to assess the impact of one sector of tourism on another without taking into account the complexity of the entire system and its integrative nature. The result has been a changing conception of the tourist, and especially the frequent traveler, from an individualized commodity to a highly sophisticated consumer factor in international political economy.

The issue of the frequent traveler is a good illustration of the international tourism consumer category identified in the integrative model of tourism as international relations, illustrated in figure 1. Today's travel manager must conceive of tourism as characterized by global electronic communication networks dedicated to the movement and management of complex forms of information — the movement of people, of currencies, and of the telecommunications facilitating air, land, and sea transport. Today's frequent traveler, therefore, represents a means of achieving a number of highly important, strategic international business, financial, and policy objectives, both government and nongovernment.(3)

In other words, what the international tourism infrastructure has witnessed since World War II, and in explosive proportions in the decade of the 1980s, is the transnationalization of the communication base, often called the information communication revolution. Growth in transportation and telecommunications technologies has been the primary physical hardware mechanism providing for this transnationalization of the communication process. In the human software dimension, growth in world population, wealth, education, and commerce, especially in the industrialized countries, has accounted for acceleration of transnational travel to unprecedented levels. This process has been supplemented by the advent of communication technologies, especially those with tremendous financial applications, such as fiber optics, satellites, facsimile, telex, and computerized reservation systems (CRS). The introduction of jet aviation in the 1940s similarly parallels a diversification and expansion of telecommunications technologies. This reflects a direct involvement of citizens, in the form of tourism consumers, in the global network of communication and financial flows with the private sector playing a key role.

The transnationalization of the communication base through international tourism is an interlocking process. In response to the explosion in distribution of world travel, competitive pressures encourage technological innovations in and modernization of the worldwide tourism infrastructure in terms of global reservations and travel related services. In response to the increasing distributive power of telecommunications technologies, such as computerized airline and hotel reservation and credit card authorization systems, frequent travelers' sensitivity to issues of quality and price increases while their tolerance for constraints on greater travel choice and flexibility decreases.(4)

Figure 1

2. International Tourism Background

To make clear the dimensions of the international tourism flow encompassing the frequent traveler, following are some stunning statistics [5]. [International tourism as defined by the World Tourism Organization is a trip of a 24-hour sojourn in another country.] International tourism evolved in a climate of expanding world trade and rising production, employment, and income in virtually all industrialized countries.(6) Travel and tourism accounted for nearly $2 trillion in sales in 1987. Total world tourism arrivals in 1988 of approximately 350 million represented a gain of 8.7 percent over 1987 figures. Tourism ranks as the largest industry in the world in terms of employment (101 million people, one of every 16 workers) and ranks in the top two or three industries in almost every country on nearly every measure. In virtually every country, the industry is as large as--and in many countries larger than--the entire agricultural sector or major manufacturers (autos, electronics, steel, textiles) considered integral parts of economic policy. Complex inter-industry interdependence of tourism products and services indicate that each billion dollars in travel sales generate close to $2 billion in aggregate output.

Between 1986 and 1999, international trips (counting all trips across international borders regardless of duration) are predicted to increase from 500 to 910 million with real travel spending (excluding fares) rising from $189 to nearly $288 billion at constant 1985 relative prices and exchange rates.[7] Projected figures for the year 2000 are 731 million in world international tourism arrivals and $386.1 in receipts (excluding international passenger fare payments).[8] Concomitant with the accelerated numbers of international travelers and frequency of travel is the increasing wealth, cross-cultural exposure, and rising expectations of the frequent traveler in market oriented economies.

3. International Business Travel

To compete in today's globalizing tourism infrastructure, therefore, tourism related corporations and institutions have been forced to differentiate their services through the development of innovative programs that reduce reliance on price competition. The full fare frequent business traveler, concentrated in large corporations and in both the service and manufacturing industries, has become the logical target. Although profiles of the frequent business traveler vary, common characteristics include: travel costs are met by an outside source; travel purpose is not discretionary; and transaction value and income is higher than average.(9) In the United States, for example, 20 percent of frequent business travelers live on the East or West coasts and are traveling further and increasingly by plane.[10] In 1986 it is estimated that 17.5 million or 32 percent of adult air passengers were business travelers, 40 percent of all trips were taken for business purposes, and that these trips generated 46 percent ($60 billion) of the industry's $64 billion of passenger revenues.[12] There were an estimated 32 million international passenger arrivals for business or conventions in 1986, representing 14 percent of the estimated total of 221 million arrivals in that year.[13]

4. Frequent Flyer Programs

The development of airline frequent flyer programs in the late 1970s is an example of an effective marketing strategy devised to meet the need "for differentiating airline services and appealing directly to the traveller, who, in many instances, is different from the purchaser of the ticket."(14) It is estimated that roughly 20 to 25 percent of airline traffic in general consists of travelers accruing benefits in airline frequent flyer programs and that 72 percent of business travelers participate in one or more programs, compared with only 23 percent of leisure tourists.(15)

Little known as recently as ten years ago, frequent flyer programs have multiplied internationally throughout the 1980s becoming a well-known, integrative component of contemporary air, land, and sea travel. The Airline Deregulation Act of 1978, created to increase competition, served to consolidate the U.S. airline industry down to five major carriers (American, Continental, Delta, Northwest, and United), and to proliferate frequent flyer incentive programs designed to secure traveler loyalty. The resulting diversity in air travel rules, regulations, and offerings is a confusing specter for today's frequent traveler. "With deregulation, there isn't a simple answer to anything."(16)

In the United States, American Airline's AAdvantage program, initiated in May, 1981, became the industry pace setter for what rapidly became globalized market practices centering around the frequent traveler concept. The original AAdvantage program paid bonuses to American Airline passengers who flew 12,000, 20,000, 30,000, or 50,000 miles on the carrier in one year. These bonuses included, respectively, upgrades from coach to first class, travel discounts from 25 to 50 percent, and free first class round trip tickets to any American destination.(17)

On July 13, 1981, Braniff, in perhaps the first salvo of cut-throat competition, offered credit on its new frequent flyer program to any American Airlines frequent flyer participant willing to switch.(18) Also on July 13, United and Texas announced initiation of their programs, and the race to gain the attention and patronage of the frequent traveler had begun. By July 16, Continental announced its Flightbank program (referred to at one time as Flightbonus) which was to become critically important to the future integration of transnational banking into the international tourism infrastructure. In addition to the more standard air mileage awards toward free travel and increased seating privileges, Continental shortly became the first to offer additional bonus points (with a cash-equivalent between $10 and $20) for travel booked with a Carte Blanche credit card.(19) Although to be among the first and of

credit cards in the travel industry. Continental's program increased the integration of transnational financial institutions into the international tourism infrastructure. This tying of the frequent traveler to a particular mode of travel finance enhanced the complexity and distributive power of the links between individual frequent travelers and the transnational bank and nonbank credit card industry.

By July 27, 1981, with Northwest's program announcement, all the major U.S. airlines were on board with some form of frequent flyer program. By August 24, 1981, Western Airlines had introduced the first "one-card" system in the industry. Western developed the wallet-sized card to provide passengers with credit facilities, automatic membership in its VIB (very important business) frequent flyer club, and entry to its Horizon Club Airport lounges. The card, which included the right to cash personal checks up to $50 at any Western ticket counter, was developed "in direct response to the needs of our frequent travelers who asked for this kind of convenience and extra service."(20)

Within the same period, major domestic and transnational hotel chains, such as Travel Lodge, British Transport Hotels, Hilton International, and Inter-Continental Hotels formalized their frequent guest packages to include discounts on rooms, guaranteed reservations, increased quality of in-room services, executive floors, etc. More important, however, was the establishment by August, 1981, of club cards, such as the British Transport Hotel's Night and Day Card, and the increasing recognition of the need for hotel business facilities with electronic document transmission capabilities.

Subsector linkages among airline frequent flyer and hotel frequent guest programs with reduced-rate car rental incentives fostered rental industry majors such as Hertz and Alamo to come up with frequent user programs of their own.(21) Made possible primarily through innovations in computer technologies, these links, in turn, triggered increasingly complex economic and information based interdependence throughout the tourism infrastructure.(22)

Of particular interest to this study are the distributive breadth and complexity achieved by these programs in less than a decade through the application of communication technologies. There is an increasingly noticeable tone in the contemporary travel literature that the base of frequent traveler programs, viewed here as an information communication process, has become overly distributed. Profitability and effectiveness are at stake. The U.S. airline, hotel, and car rental sponsors of frequent flyer and frequent guest programs, recently are coming under pressure -- fostered by globalization, increasing expenses, and tighter controls -- to curtail or transform their frequent traveler programs into more closely targeted marketing. Ironically, what is operating, both the capability as well as the necessity for such a transformation is the greater use of sophisticated tracking systems and computer data bases essential to the targeting of actual users of frequent traveler programs. "The international market is 'the new frontier' of the frequent user programs."(23)

5. American Airlines AAdvantage Program

Recent changes at American Airlines, historically an aviation industry innovator, is a good example of transnational airline response to contemporary pressures on industry approaches to the frequent traveler and frequent flyer programs. Rather than curtailing operations, American is enacting a plan for services improvements based on 18 months of research and development. In April, 1990, American announced plans for an $11 billion investment over the next five years "to expand its service so that it can compete effectively with foreign flag carriers." Investments included $7.7 billion on 34 MD-11s, Boeing 767-300s, and Airbus A300 for international transit, $655 million in terminal expansion at international airports and U.S. gateway cities (including high-tech baggage systems, more and expanded Admirals Clubs, improved check-in and screening facilities), and $3.4 billion on improvement of services in general.(24) American's focus is on improving first- and business-class travel(25) through introduction of its new "International Flagship Service." With its newly acquired Latin American routes, American will be offering 145 trans-Atlantic flights a week.(26)

Comparable to the U.S., and conceivably transnational, travel industry at large, American is faced with overextension in the distribution of its frequent flyer programs. Its frequent flyer club, AAdvantage, begun in 1981, had two million members by 1984 and 11 million by 1990.(27) Without owning Sabre, its own computerized reservation system, American would be swamped with information overload in tracking the universalizing communication base of its own frequent traveler "family." This is not to mention the additional, enormous transactional information flows through Sabre CRS of international tourists not aligned with its programs. As it is, it is estimated that American carries the potential liability of close to 70 billion unused miles accumulated by its frequent flyers on its balance sheets. This backlog has swelled substantially since the triple mileage awards started by Delta in 1988, which were matched, through force of competition, by airlines throughout the industry.

American borrowed a 1970s frequent guest technique from the transnational hotel industry to become the first airline to offer a new airline package swapping frequent flyer miles for tangible, often luxury goods and commodities. It marketed these through a 32-page color catalog.(28) American pays virtually nothing for these items to the 20 plus advertisers involved who feel adequately recompensed through the value-added distribution exposure they gain from access to American's frequent flyer mailing list, an issue in information privacy all its own. The offerings

range from mink coats and floor clocks to personal computers, player pianos, and financial instruments, and involve negotiating a price and cashing in a set number of miles to get a further rebate.(29) For example, for 20,000 miles, certificates of deposit may be purchased at lower than market prices and higher yields. Caught in its own integrated distribution network, American is vulnerable to one unforeseen circularity in its new promotion. That is the ability of a frequent flyer to reduce the mileage being drained from his or her mileage bank through payment via a credit card linked to American's frequent flyer program, worth on certain credit cards one mile for every dollar spent.(30)

6. Emphasis on the Human Dimension:
Frequent Flyer Clubs

Globalization of travel and its close association with telecommunication technologies, consequently, is demanding greater emphasis on the human dimensions of the international tourism infrastructure, particularly on travel and transportation industry employee education; however, it is the advertising techniques combined with the best American and European promotional know-how that has captured the international market. Staffing of frequent traveler programs now requires cross-cultural as well as managerial knowledge of languages, travel regulations, and currencies. Experienced computer reservation system vendors are crucial elements in the monitoring and tracking of strategic information flows embodied in frequent traveler airline and credit card computerized records. An increasing multiplicity of transnational airline alliances and joint ventures, made viable by telecommunications technology, are changing the very nature of the frequent, international travel experience. For example, on April 9, 1990, Swissair and Delta introduced their European Travel Invention. Based on a so called "modular package concept," the program stresses flexibility and individual selection by clients of various "vacation elements (air, rail, Kemwel rental car, optional tours, and locations throughout Switzerland and Europe) to suit their desires."(31)

In the face of the very telecommunications technologies making such frequent travel programs possible is the increasing recognition of the human dimension within the international tourism industry, of the salability of ambiance or "personalized treatment as a luxury"(32) -- old wine in new bottles. Lounge clubs and loyalty clubs are the primary mechanisms transnational airlines have discovered to personalize their service to the frequent traveler. The club power of appeal is controlled through limiting membership access. Less elite lounge club facilities at airports are accessible for a fee. Loyalty clubs are designed to reward the dedicated frequent traveler and often are open only by invitation to a controlled low enrollment number. "Just how special the treatment is usually depends upon how good a customer you are; you have to earn your way in."(33)

A good example is British Airways, which offers four clubs. Most exclusive is its Premier Club, based on an expenditure of $40,000 or more annually on British Air flights. Club membership, currently at 900 (ceiling of 2,000) is by invitation only. Members receive top priority on everything, a BA Air Plus travel charge card, a personalized toll free reservations number, priority recognition, lounge access with guests at any time, complimentary insurance coverage, and discounts on hotels and car rentals.(34) Australian Airlines Flight Deck Club, on the other hand, costs approximately $150 to join, with an annual $200 fee. Among many privileges, club benefits are globally distributive through reciprocal club use agreements with Northwest Airlines World Clubs, British Airways Executive Clubs, Air New Zealand Koru Clubs, Cathay Pacific Marco Polo Clubs, Canadian Airlines International Empress Clubs, and United Airlines Red Carpet Clubs.

Foreign carriers have been slower than their U.S. counterparts to integrate frequent traveler programs into their operations. This is due partly to their lower starting position in 1980 in computer reservation systems technology -- virtually prerequisite for the movement and management of multi-faceted frequent flyer travel arrangements, mileage awards, and other benefits. Also, until recently, it mainly has been only their U.S. and Canadian passengers who expected such luxury services.(35) By 1990, however, the worldwide distribution of foreign airline club privileges reflected the diffusion of American transnational marketing techniques which in turn were made possible by global expansion of American computer technologies, such as airline CRS. This has contributed to furthering the links between transnational carriers through the international tourism infrastructure. For example, in addition to its own frequent flyer program for corporations, Lufthansa has partnerships with Delta, Eastern(36) and Continental, United, and USAir. Similarly, Japan Airlines has offered is own program since 1983 but is also a member of the Delta Frequent Flyer plan.

Frequent Traveler Programs and
International Relations

The relationship of frequent traveler programs and telecommunications technologies comes quickly to the level of international relations policy when power and national sovereignty are at stake. From an international relations perspective, the frequent traveler, especially frequent flyer, phenomenon suggests convergences taking place in power and control of the tourism distribution process. The effect on business travel by U.S. Department of State travel advisories for certain regions of the world during the Persian Gulf War is one example of this influence. Financial and technological incentives as well as disincentives, in other words, now may tend to favor those nation states served by transnational technological and financial networks as well as air carrier suppliers and advertising techniques. An understanding, then, of who is benefitting and

who is leading increasingly may become a function of who is controlling access to the economic resources, ownership, production, and, most critically, the distribution of transnational information and human flow in the frequent traveler process.

In today's global economy, instruments such as communication, organizational and advertising skills, and manipulation of travel markets have become important sources of power. Thus, countries, such as the United States, Germany, and Japan, which foster transnational firms are becoming more powerful in the international scene. Added to this, American and European long-time experience in market and advertising techniques are becoming crucial elements in intangible sources of power.

The diversity and complexity of participants involved in the tourism consumer category of the tourism infrastructure as international relations model provides a useful framework for examining national sovereignty, a concept of paramount importance in international relations. Through tourism, a plethora of actors other than nation states participates directly in world politics. The transnationalization of airlines through joint marketing agreements centering around the frequent traveler is a good example. The concept of the frequent traveler, and especially the frequent flyer, is primarily an invention of the U.S. travel, particularly airline, industry within the last decade. Viewed in this study as part of an information communication process, links among airline, hotel, and car rental frequent user programs have grown in distributive power and complexity throughout the 1980s.

The rapid adoption of frequent flyer programs and club privileges by foreign airlines shows the diffusion of American marketing techniques throughout the international system. Not only American technologies but also American advertising and marketing strategies are expanding globally establishing supernational relationships through travel agreements among transnational air carriers. The increasing level and geographic distribution of such international interactions are contributing to the erosion of the conditions upon which traditional conceptions of national sovereignty are based. It is not that the importance of nation states as coherent units and dominant participants in world politics is disappearing. Rather, it is that the conditions underlying contemporary interactions are changing, shifting the political processes at times away from traditional definitions in the direction of linkage strategies and agenda setting characterizing new transnational and transgovernmental relations.(37)

The complexity and integrative nature of the tourism infrastructure in the area of transnational air carriers illustrates this well.(38) Bilateral and multilateral economic and trade relationships among transnational air carriers, including CRS agreements and financial networks, are expanding. This connectivity has important implications for traditional concepts of national sovereignty and power through ownership and control of electronic distribution of capital and information. Participants other than nation states, such as American Express, virtually every transnational airline, AT&T, Electronic Data Services, Citicorp, etc., are emerging as major participants. This is opening the way for an increasing supernational role for international organizations and transnational corporations in the political processes surrounding transgovernmental relations.(39) As the products, markets, physical plants, research facilities, and ownership of major corporations go global, the concept of clear national identities is diluted.(40)

The transnationalization of United Airlines and American Airlines frequent flyer programs is a good example. In 1984, United Airline's Mileage Plus program served 153 cities and boasted two million members. Members of this frequent flyer group who journeyed 350,000 miles or more on the airline were entitled to a 24-day South Pacific cruise for two. Since 72 percent of business travelers today participate in one or more frequent flyer programs, the time consuming nature of this award may well have been difficult for the high mileage, constantly traveling business awardees to redeem. In response, American Airlines -- burdened (as were United and many others) with the accumulated accounting liability of millions of unclaimed frequent flyer free miles -- by the end of the decade initiated its mink-coat-for-miles, commodities-based travel loyalty award program. The concept of diversification and diffusion of ownership and control of frequent traveler program agreements and incentives was imitated by other U.S. and foreign air carriers.

The most recent offering of American's AAdvantage Program is a "Dial For Miles" joint marketing agreement with MCI, announced February 26, 1991. In this unique integration of telecommunications and travel networks, of electronic information flow and physical flow of people, MCI and American Airlines offered five AAdvantage miles for every dollar spent on MCI residential long distance calling. The service applied to calls everywhere in the U.S. and to over 180 countries and places worldwide, with a 500 AAdvantage mile bonus just for signing up. A personal MCI/AAdvantage charge card for credit calls issued to subscribers linked the program to back office financial networks which kept track of both minutes and miles. In an effort both to expand business and universalize its telecommunications base, MCI tapped into American Airlines transnational frequent traveler network, linking international communication with international tourism. Electronic capital flows and credit and information data bases, thereby, become shared resources making economies of scale in travel, telecommunications, and financial services more accessible.

Similar joint ventures, marketing agreements, and consolidations between major transnational organizations in the area of telecommunications, transnational finance, and transportation further illustrate the changing nature of power,

information, and capital in international relations. United Airlines, for example, as early as 1984 had established transnational frequent flyer and joint marketing agreement tie-ins with Air France, Air New Zealand, Lufthansa, and SAS, plus U.S. domestic links with Hertz, Budget Rent A Car, Westin Hotels, Royal Viking Line, Braniff, and seven regional airlines. United Airlines, therefore, for 150,000 miles in 1984 was able to offer its program members two round-trip first class tickets to Hong Kong or Tokyo on United, two round-trip coach tickets on Air New Zealand, one round-trip first class ticket on Lufthansa or two round-trip first class tickets on Air France.(41) In so doing, United Airlines' frequent traveler program, not illogically, linked frequent travelers with a selection of largely industrialized travel destinations. A more recent example was in February, 1991, during the peak of the Persian Gulf crisis when United Airlines offered free round-trip tickets to travelers subscribing to its new nonstop Chicago-Tokyo route. These tickets, rather than free to anywhere, were restricted to travel within the U.S., Mexico, and the European Community.

In conclusion, through technological and financial convergences taking place in international tourism, major transnational travel, telecommunications, and financial corporations are gaining the ability to control the flow of large numbers of tourism consumers and, consequently, millions of dollars in travel-generated revenues. From the perspective of national sovereignty and economic power, the direction of this flow is of critical concern. In this light, the distributive nature of airline frequent traveler programs illustrates the role of telecommunications in the tourism infrastructure and its increasing influence on the process of globalization.

The Future of Telecommunications and The Travel Industry: The Case of Hawaii 1991-2006

Alice Chan Plummer
Department of Communication
University of Hawaii
Honolulu, U.S.A.

1. ABSTRACT

The relationship between telecommunications and travel and its ramifications has increasingly become an important topic of inquiry. This paper first provides a brief overview of this relationship. Next, it discusses the results of a fifteen-year forecast on future directions of telecommunications and travel in the State of Hawaii between 1991 and 2006.

2.1 BASIS OF THE STUDY

In recent years, there has been increasing interest in studying the relationship between telecommunications and the travel industry. Commonly addressed as "Triple T" [Telecommunications, Tourism and Transportation], this area of research attempts to examine the implications of these three sectors on society from an integrative perspective.

The Hawaiian Islands are well known for their world-class hospitality industry. With such fame comes the heavy reliance of the Aloha State on its travel industry for socio-economic prosperity, such as contribution to the Gross State Product, generation of employment opportunities and stimulation of economic activities. Because of the great importance of its visitor industry, Hawaii serves as an exemplary case to study the relationship between telecommunications and travel in the existing information era.

2.2 OBJECTIVES

The first objective of this paper is to provide a brief overview of the relationship between telecommunications and travel. In doing so, the role of telecommunications in travel and the changes brought about in the latter will be briefly discussed in Sections 3.1 and 3.2.

The second objective is to assess the future of telecommunications and travel in the State of Hawaii from 1991 to 2006. Using the Delphi Technique, which is introduced in Section 4, the results of the study are summarized in Section 5. This paper then closes with the limitations and conclusion sections.

3.1 TELECOMMUNICATIONS APPLICATIONS IN TRAVEL

Approximately US$ 2 trillion is spent each year on the travel industry throughout the world, which accounts for 23% of global GNP (Miskin, 1990). At present, the travel industry is the biggest source of demand for sophisticated telematics. Information systems have become a strategic competitive advantage to the travel industry (Doll, 1989). In turn, flight information made available through such information systems assumes the role of a strategic competitive factor.

3.1.1 COMPUTERIZED RESERVATION SYSTEMS

The most commonly known form of telecommunications applications in the hospitality industry is that of computerized reservation systems [CRSs]. In 1987, American Airlines made roughly 10,000 fare adjustments per day (Aquino and Cruz, 1990). The month of October 1986 alone saw 4 million such fare adjustments! Furthermore, it is not uncommon to find that no two seats on a flight are sold at the same price. Such fare manipulation is virtually impossible to accomplish manually, thus making it easier to comprehend the heavy reliance of the airline industry on CRSs. In addition to keeping track of sales and seat allocations, CRSs are proving to be major profit generators as well. By keeping low-fare seats to a bare minimum to fill the planes, the rest are sold at a profit.

Today, CRSs have also been widely adopted by lodging businesses. Furthermore, rental car companies, such as Avis and Budget which issue the Wizard Card and Rapid Action Card, respectively, to regular clients also utilize automated reservations (Oliver, 1988).

One way in which airlines, hotels and rental car companies can make use of their CRSs to generate revenue is through charging travel agencies and other end-users, such as corporate travel information centers, fees to access their information systems. In addition to such immediate gain, long-term insurance of profit comes from loyalty to the information system (Bailey, 1989): whichever carrier can get its CRS most widely adopted will have a higher chance of getting more bookings than other competing airlines, and in turn, more sales.

3.1.2 OTHER APPLICATIONS OF INFORMATION SYSTEMS, TECHNOLOGIES AND NETWORKS IN THE TRAVEL INDUSTRY

In addition to facilitating reservations, telecommunications capabilities are also employed in the hotel businesses to enhance hotel operations and guest services. Property management systems [PMSs], as information systems in the hotel industry are commonly known, include the use of such applications as point-of-sale technologies, automated check-in/check-out systems, pay-per-view movies and voice messaging.

The latest feature available in pay-per-view technology is on-demand programming. Viewers no longer have to wait for specific show-times, but can enjoy any movie at any time of the day they desire.

With respect to the telephone system, automated voice mail features are gradually being implemented. This is particularly valuable in solving the language problems with calls for hotel patrons who are from overseas. Other features, such as call accounting and call transmission will also be experiencing continual upgrades.

Furthermore, telecommunications applications are gradually being adopted in back-of-house support systems, such as in monitoring electricity and security/surveillance. A recent innovation in electronic security in hotels is that of the extension of guest-room card keys to on-line security.

ISDN. Information transfer of large volumes and diverse nature is a critical component of the hospitality businesses (Portugal, 1991). Because of such information needs, ISDN, which incorporates voice, image and data, will be a suitable application to the travel industry.

Videotex. Videotex is a system that is a promising candidate for offering up-to-date on-line travel information. An example is the French videotex system, Minitel, which proves to be most successful in its services dedicated to travel. Potential travellers can conveniently pick their destination, arrange for their travel and accommodation (Rouet, 1991). Other success stories in videotex travel information services are offered by Australia's Aftel and the Republic of China's Chinese Videotex System [CVS].

VSATs. Very small aperture terminals form the information systems backbone of some hotel chains, such as Holiday Inn. These satellite dishes provide low-cost one-way, receive-only communication and two-way transmission of video, voice and facsimile by time-sharing or frequency-sharing.

Telecommunications Hubbing. Hubbing provides cost and operational efficiency and flexibility in telecommunications networking for travel information to be transmitted among different points of the network. SITA is a perfect example. With more than 750 centers and access nodes, the SITA network relies on the hubbing concept to provide information and telecommunications services to 400 airlines and associated industry members in 184 countries in the world (Crawford, 1991).

Automated Ticketing Services For Travel Agencies. Among few new network services available to travel agencies are satellite ticket printers [STP] and electronic ticket delivery networks [ETDN], which both automate ticketing (Darby, 1991). The STP vendors get part of the commission of travel agents for ticket printing, while ETDN vendors charge a flat rate.

3.2 IMPACTS OF CRSS AND OTHER TRAVEL INFORMATION TECHNOLOGIES, SYSTEMS AND NETWORKS

Having seen several types of telecommunications applications in travel, this section discusses some changes brought about in the hospitality industry.

3.2.1 ALLIANCES AND MERGERS

After deregulation of the airline industry in the United States, coupled with the transition of the industry to becoming heavily reliant on information systems, smaller regional US airlines were not able to compete. Consequently, they either formed alliances with larger carriers, merged with other small airlines, or sold out (McGee & Burdick, 1986). Even the mega-carriers themselves have been trying to take advantage of alliances with each other.

At the international level, carriers ally with each other to expand their operations. For instance, in 1987, British Airways and United Airlines made an agreement to integrate their networks and flight schedules (Cotter, 1988). The alliance also includes code sharing, where the allied commuter airline's services are recorded under the host airline's two-letter reservation code in its CRS (Oster & Pickrell, 1986).

In addition to "inter-airline" cooperative efforts, telecommunications firms have also been sought to provide technical contribution to join force with management and business skills in the travel industry. In 1990, for example, Electronic Data Systems [EDS] acquired half of Texas Air's CRS for $250 million. This is in addition to $4 billion worth of anticipated contracts over the next ten years (Reier, 1990).

Another type of strategic cooperation common to the travel industry is that of horizontal alliances, where an airline, a hotel and a rental car company agree to cooperate in their information systems, marketing efforts and other joint endeavors. Examples are the alliance among American Airlines, Sheraton Corp. and Avis Inc., as well as the partnership of United Airlines, Westin Hotels and Resorts, Hertz Corp. and Covia Corp in their multinational CRS called Allegis (Agnew, 1987).

3.2.2. DISINTERMEDIATION

Disintermediation entails the concept of eliminating the "middle man" between the producer and/or wholesaler of a product or service and the consumers, with transactions made directly between the seller and the buyer. In the context of tourism and transportation, the "middle men" are the travel agencies and brokers.

Direct access to information and reservation systems presents potential threat to these intermediaries. At present, with the use of a computer and a modem, one can access on-line travel information networks and arrange for one's own bookings. An example is the electronic edition of the Official Airlines Guide [OAG/EE] which, in addition to enabling travellers to make instantaneous reservations, provides most up-to-date flight information and permits search for the cheapest fare (Levitan, 1988). Compuserve is another system that offers a wide range of information on travelling.

There exists the argument that rather than being threatened by the availability of CRSs and other travel information networks, travel agents will actually benefit from these technologies by having their workload in information gathering, bookings and confirmation reduced considerably and made more efficient. The key is to be able to implement a strong information-systems base in their offices to access the industry's travel information.

4. THE DELPHI TECHNIQUE

The Delphi Technique is employed to achieve the second objective of this paper: to develop a fifteen-year forecast on the future of telecommunications and the travel industry in the State of Hawaii from 1991 to 2006.

Delphi is a systematic approach that utilizes expert opinion to deal with complex problems (Wedemeyer, 1985). It is a valuable tool to both forecasting and structuring group communication. Furthermore, this method is especially useful during the early stages of planning, such as scenario development or goal setting.

Normally, a Delphi study consists of two-to-three rounds of questions about the topic under study. The process of administering the study is characterized by (1) structuring information flow, (2) feedback to participants, and (3) anonymity for the participants (Linstone, 1978).

5.1 THE DELPHI STUDY

For this study, two rounds of 49 questions on highly possible and significant future developments in Hawaii's telecommunications and travel industries were mailed to 105 experts selected from local industry, government and academia. 51 responded to the first round and 32 to the second.

Out of the 49 questions, 31 are trends, which depict changes in developments overtime [growth, retardation, etc.]. They fall into five groups:

- o General Trends
- o Technical Trends
- o Economic Trends
- o Market Trends
- o Social Trends

The remaining 18 questions are events, which represent sudden changes [policy intervention, emergence of new services, etc.]. They are categorized as:

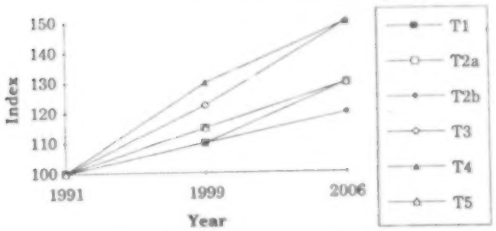
- o Systems/Services Events
- o Regulatory Events
- o Socio-economic Event

5.1.1 GENERAL TRENDS [T1 to T5]

The general trends are formulated to draw expert opinions on the overall

macro-outlook of where telecommunications and travel are heading in the coming fifteen years. In sum, the view of the expert participants is a conservative one; they do not see much dramatic growth or changes [see Figure 5.1.].

Figure 5.1. General Trends



T1 = overall quality of telecommunications systems
T2a = increased efficiency of operations with use of info. tech.
T2b = improved quality of guest services with use of info. tech.
T3 = visitors' demand for telecommunications services
T4 = availability of travel info. via electronic delivery
T5 = info. systems as competitive technological advantage to travel

5.1.2 TECHNICAL TRENDS [T6 to T13]

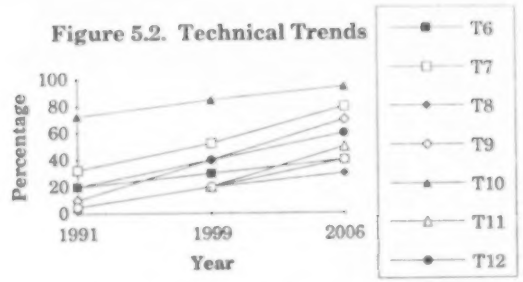
All of the technical trend questions, with the exception of T13 [advertising of travel through digital interactive multimedia channels], relate to the information systems infrastructure in the hotel industry. This is an attempt to assess the extent to which telecommunications technologies have been, and will be, applied to facilitate the everyday operations of hotels and resorts in the State of Hawaii. Figure 5.2 presents a profile of these seven hotel information systems trends.

5.1.3 ECONOMIC TRENDS [T14 to T15]

In order to gauge how dependent Hawaii's economy is on its travel industry over the coming fifteen 15 years, T14--visitor expenditure as percentage of total annual GSP--was included in the questionnaire. According to the estimates given by the expert panel, 48% and 50% of Hawaii's GSP by 1999 and 2006, respectively, will be generated directly and indirectly by the travel industry.

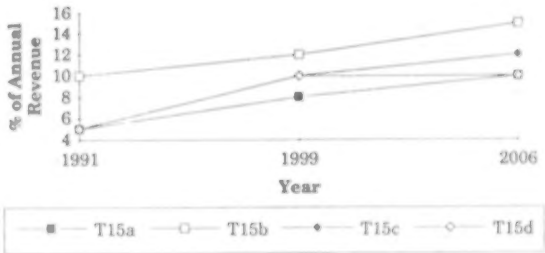
T15a to d ask for expert projections on the investment levels in information systems in the travel industry as a whole and the different segments, i.e., airlines, hotels and travel intermediaries. The results are shown in Figure 5.3.

Figure 5.2. Technical Trends



T6 = % hotels/resorts with convention/conference centers
T7 = % hotels/resorts with automated check-in/check-out systems
T8 = % hotels/resorts with in-house teleconferencing facilities
T9 = % hotels/resorts with automated voice mail/messaging services
T10 = % hotels/resorts with pay-per-view programs
T11 = % hotels/resorts with additional phone jacks in guest rooms
T12 = % hotels/resorts with electronic back of house support systems
T13 = % marketing of travel through electronic multimedia

Figure 5.3. Investment in Information Systems



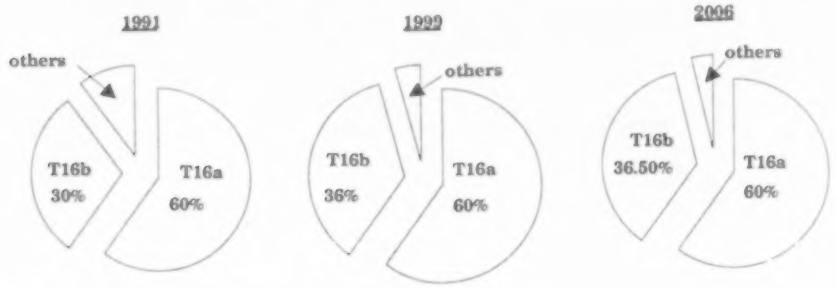
T15 = Investment in info. systems as % total annual revenue of
a = the entire travel industry
b = the airline industry alone
c = the hotel industry alone
d = travel intermediaries

5.1.4 MARKET TRENDS [T16 to T20]

In order to assess the level of disintermediation, if any, that will likely take place in the state's travel industry, T16a and b were formulated [see Figure 5.4]. A possible interpretation of the projections is that additional sales resulting from an expanding market will tend to be captured by the airlines and hotels themselves.

Regarding the size of the state budget for travel being spent on advertising and marketing [T17], it is estimated to remain unchanged between 1991 and 1999,

Figure 5.4. Distribution of Market Shares in Total Annual Sales in Travel

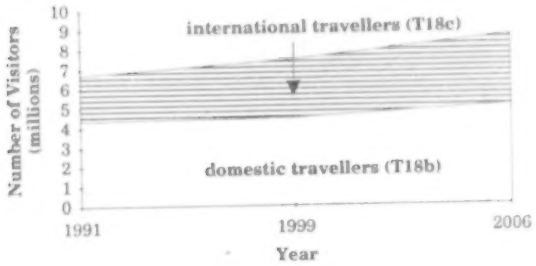


T16a = % total annual sales in travel made through travel intermediaries
T16b = % total annual sales in travel made directly between travel services producers and customers

i.e., at 25%, while increasing to 28% by 2006.

The rest of the market trend questions are intended to estimate the total annual number of visitors to the Aloha State between now and 2006 [T18a], the ratio of domestic to international travellers [T18b:T18c], percent of T18a being business travellers, and in-bound business trips that can be substitutable by teleconferencing. [See Figures 5.5 and 5.6.]

Figure 5.5. Total Annual Visitors (T18a)

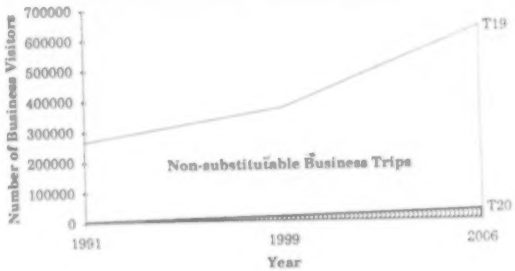


The percentage of visitors to Hawaii being domestic travellers will decrease from 65% at present to 60% by 1999 through 2006, while there will be a parallel increase in international arrivals.

5.1.5 SOCIAL TRENDS [T21 to T24]

The four social trends are intended to draw the employment profile of Hawaii's travel industry between 1991 and 2006. Figure 5.7 shows the percent of Hawaii's work force directly employed by the travel industry [T21] and the percent of travel personnel with knowledge of at least one more language other than English [T22].

Figure 5.6. Business Trips to Hawaii: Substitutable and Non-substitutable



T19 = % visitors being business travellers
T20 = % in-bound business trips substitutable by teleconferencing

According to the projections for T23, 8% of the travel industry employees will be telecommunications/information systems workers by 1999, and the figure will increase to 11% by 2006. Furthermore, by 1999 and 2006, 4% and 5% of these travel information systems personnel, respectively, will be teleworking from home or a remote telework center.

E8a = fully-automated ticketing in major tourist sites
E8b = fully-automated ticketing throughout state
E9 = request/order of hotel services by videotex
E10 = guest message handling by videotex in major hotels

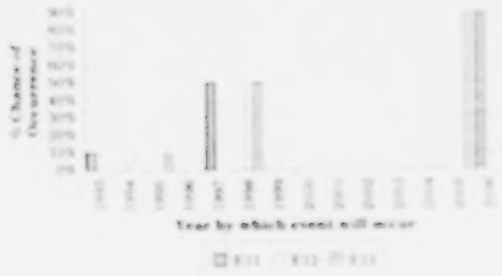
5.1.6 SYSTEMS/SERVICES EVENTS [E1 to E10]

These event questions provide estimates on: [1] new systems for travel information; [2] new features in the phone system; and [3] automation in travel, as shown in Figure 5.8, 5.9 and 5.10.

5.1.7 REGULATORY EVENTS [E11 to E13]

The first regulatory event, E11, relates to the controversial issue of shared tenant services [STS] being approved, allowing hotel/condominium owners to by-pass the local phone company in offering their own telecommunications services to patrons [see Figure 5.11]. E12 is a projection on the chances of a bill granting tax credits for teleworking [E12] being passed by the State Legislature. The last regulatory event question asked is GTE Hawaiian Tel being allowed to enter the entertainment industry in offering video switching services [E13].

Figure 5.11 Regulatory Events



5.1.8 SOCIO-ECONOMIC EVENT [E14]

This event considers an economic catastrophe scenario, such as a recession, an international or a regional political crisis, with an impact on Hawaii's travel industry that is at least as sizeable as that of the Middle-East crisis in 1991. It is highly agreed that such an event has a 50% chance of occurring as early as within the coming four years, and a 90% chance of happening by 2000.

5.2 TELECOMMUNICATIONS AND TRAVEL: HAWAII 1991-2006

Based on the projections of the developments presented in 5.1 and their ramifications, a number of important conclusions regarding the future directions of telecommunications and travel in the State of Hawaii between 1991 and 2006 can be drawn. These conclusions are listed as follows under three categories: [1] Telecommunications Needs and Usage; [2] Investment in Information Systems; and [3] Travel and Hawaii's Economy. Placed in parenthesis after each concluding point is/are the specific trend[s] and/or event[s] based on which the conclusion is drawn.

5.2.1 TELECOMMUNICATIONS NEEDS AND USAGE

- Overall quality of information systems and applications to travel in the State of Hawaii will advance at a very slow pace between 1991 and 2006. [T1-T5]

- Information technologies are projected to be able to more effectively enhance operational activities, such as reservations and billing, than to improve the quality of services, the human end of the hospitality industry. [T2a and b]

- There will be a slight over-supply of electronic communication services in the travel industry between 1991 and 1999, suggesting that such services will not be readily absorbed by intended users, i.e., visitors to Hawaii, especially business travellers. [T1 and T4]

- By 1999, out of an estimated total of 375,000 business trips to the State of Hawaii, 15,000 will be substitutable by teleconferencing, and 31,900 out of 418,000 by the year 2006. However, owing to the presence of incentive travel, there is uncertainty as to the number of these trips that will actually be substituted. [T20]

- The increase in international visitors suggests growing demand for special telecommunications services/features, such as long-distance calling and language translation. [T9, T18a and b, E3 and E4]

- By 1999 and 2006, respectively, 8% and 11% of those who are directly employed by the travel industry, the latter of whom will constitute about one-third of Hawaii's work force, will be working in telecommunications/information systems divisions/departments. [T23]

- By 1999, out of every 1000 travel information systems workers, 40 will be teleworkers, and the number will increase to 50 out of 1000 by 2006. [T24]

- With availability of in-house conference centers and teleconferencing facilities, the hotel industry can expand its ability to attract and serve business patrons instead of just relying on vacationers for income. This will especially be valuable during off-seasons of tourism. [T6 and T8]

5.2.2 INVESTMENT IN INFORMATION SYSTEMS

- Investment in information systems as a percentage of the total annual revenue of the entire travel industry will double between 1991 and 2006. [T15a]

- The airline industry will be the leading segment of the travel industry in investing the highest percent of its total annual revenue in information systems. It will be increasing its investment in

information systems by 50% between 1991 and 2006. [T15b, E6, E7 and E8]

- The hotel industry will be the leading travel segment in increasing its investment in information systems as a percentage of its total annual revenue between 1991 and 2006, such investment will increase by 120%. [T15c, T16 to T12, E9 and E10]

- Investment in information systems as a percentage of the total annual revenue of the travel intermediaries will double between 1991 and 2006. [T15d]

5.2.3 TRAVEL AND HAWAII'S ECONOMY

- The state of Hawaii's economy will still be very dependent on tourism in the coming fifteen years. [T16]

- The travel industry in Hawaii will be accountable for approximately half of the annual Gross State Product (GSP), while directly employing about one-third of the state's work force. [T16 and T21]

- An additional total of 800,000 tourists to the state between the years of 1991 and 1999 will be accountable for the increase in visitor expenditure as a percentage of total annual GSP from 47% in 1991 to 48% by 1999. The latter will accelerate to 50% by 2006 with another one million visitors arriving between 1999 and 2006. [T16 and T18a]

- Some degree of disintermediation will take place. Although the market share for travel intermediaries will still be relatively secure over the coming fifteen years, additional sales as a result of an expanding travel market will tend to be captured by airlines and hotels themselves. [T16a and b and E6 to E8]

- The highly probable occurrence of an economic catastrophe by the year 2000 suggests the need for some contingency planning for diversifying the Hawaiian economy, which is heavily dependent on visitors for revenue. [E16]

6.1 LIMITATIONS

The main source of limitations in this study relates to the fundamental problem of developing a reliable forecast on telecommunications and travel in the State of Hawaii between 1991 and 2006. Although the results of the Delphi study presented appears solid, the data collected pertain to the future, and as such, are of a "soft" nature. Hence, the interpreted results are mainly suggestive, and should not be treated as more reliable than they actually are.

Another limitation in this study regards a characteristic of the Delphi Technique employed, i.e., the requirement of expertise. Only two out of the 12 final respondents for this study rate themselves as travel experts, and the ten who can be considered experts in both telecommunications and travel are still relatively more confident in rating themselves highly in telecommunications than travel. Consequently, the travel-side data in the forecast are considerably weaker and less reliable than those on telecommunications trends and events.

6.2 CONCLUSION

In sum, despite the presence of limitations inherent in the Delphi Technique, the value of the forecast on telecommunications and travel in Hawaii developed in this study should not be underplayed. It serves to identify potential opportunities, as well as possible disasters and threats, and thus, can be highly useful reference for future policy making and goal setting. A note of caution to bear in mind is that the forecast is only intended to shed some light on a number of highly possible future developments, and that readers should not be overly confident of the data and results presented.

SOUTH OF THE BORDER, DOWN MEXICO WAY

Ronald W. Symes

Southwestern Bell International Development

St. Louis, Missouri USA

To paraphrase the song, "South of the border, down Mexico way, we met a company and country in which to stay".

Southwestern Bell Corporation has been extremely pleased with its decision to participate in the privatization of Teléfonos de México (Telmex). What I intend to share with you today are some of the experiences leading to our consortium ultimately being chosen by the Mexican government to purchase a controlling interest in Telmex. In addition, I will report on operations to date, what we hope to accomplish in the near term and what has gone "right" and what some of our problems have been.

Of course, as I'm sure you know, we are members of a consortium that was chosen for this purchase; we didn't do it alone. The consortium is made up of Grupo Carso, a large Mexican conglomerate, France Cable et Radio, a subsidiary of France Telecom, and Southwestern Bell International Holdings Corporation, a subsidiary of Southwestern Bell Corporation.

Before I get into the main part of this report, I think it would be appropriate to have some understanding of Telmex in terms of its size, financial results, service quality, and so forth. By way of comparison, Telmex had 4.7 million access lines at the time the transaction was completed in December of 1990. This for a population of some 80 + million people. In contrast, SWBT had 12 million access lines serving an area with approximately 25 million people. Said another way, Telmex had one line for every 15 people while SWBT had one line for every 2 people. Telmex had $3.0 billion in sales in 1990; Southwestern Bell Telephone Company (SWBT) had $7.5 billion. On any given day during 1990 there were over one million held orders for telephone service in Mexico; SWBT had virtually none. Telmex currently has 49,000 employees while SWBT has 56,000.

With this brief introduction out of the way, lets now move to the deal itself.

Based on our experience, there are two key events that must occur in privatization of Telecoms in order for a successful transaction to take place. These events must take place on each side of the negotiating table.

The event that must occur for any potential buyer to participate successfully in a transaction the size of this one sounds very basic; but in our own experience, I can tell you it is not as simple as it sounds. That event is the decision by the senior management of the corporation to fully commit the resources of that company to the project at hand. That sounds, as I said, quite simple. Senior management, by the way, includes the Chairman and Chief Executive Officer. Happily for our company, that decision was made by Mr. Ed. Whitacre early on in the time schedule that Mexico established for their privatization. What this meant to me, as SBC's man in the trenches, was that I could proceed with doing the job without having to seek approval at every step and without having to "sell" concepts at every turn.

The other event that must occur is for the selling entity to make certain decisions as well. In the case of the Mexican government, this meant deciding what their real goals were for their communications network (aside from receiving the best price).

For example, was it their desire to establish an immediate "free market" environment in Mexico for the telecommunications industry; was it to assure themselves that they would have a "world class" communications infrastructure in the near future; was it primarily a series of social goals; or was it some other goal? Fortunately for all the bidders, the government had a clear vision of its goals. Simply stated, the government believed that the Mexican economy could not grow as it desired without a "world class" communications infrastructure.

Indeed, it is my opinion (not an original thought) that no country's economy can grow beyond a certain point without such an infrastructure. Therefore, the government set goals for the privatized Telmex in terms of required growth rates, service levels, etc. and allowed for no direct competition for a period of time so that all efforts of the purchasing entity could be directed entirely toward meeting those goals. This factor also had an effect on the value that potential purchasers would place on Telmex.

Once these important activities have been accomplished, other ongoing actions had to happen so that both parties to the transaction give and receive necessary information vital to the deal.

One of the most important steps that the Mexican government took, which influenced our ongoing interest in the company, was to allow easy access to various governmental departments and agencies so that areas of concern could be readily discussed and issue resolution accomplished. This meant that we, as potential buyers, could discuss items that raised questions which appeared in the concession document and understand items that were not entirely clear to us. This in turn allowed us to better understand why the government had created certain parts of the concession. The exchange of ideas and information in these meetings gave us, as foreigners, a comfort level that would not have otherwise existed. In this same regard, the exchange of information between Telmex management and ourselves was handled in a professional and thorough manner . . . all of which went a long way toward Southwestern Bell feeling good about the deal.

Certainly not to be minimized is the matter of partners in a deal of this size. Any consortium of this type must have partners that are comfortable with each other, respect each other's areas of expertise and, in general, are able to function as one entity. By law, the controlling interest of Telmex had to remain in the hands of Mexicans. Our consortium is very fortunate to have Grupo Carso as that controlling party. Mr. Carlos Slim, president of Grupo Carso, is a businessman who commands the respect of the entire Mexican business community. He has a proven record of turning around businesses that are in trouble and then operating them profitably and efficiently. He is an engineer by training and has had an extremely varied and successful business career before becoming involved in Telmex. He is currently Telmex's Chairman of the Board. France Telecom has a proven reputation for growing and operating one of the most advanced telecommunications networks in the world. These two world class businesses, along with ourselves, proved to be an unbeatable combination in the eyes of the Mexican government. This unbeatable combination also included $1.8 billion. On 20 December 1990 the transaction was finalized.

Next, I will get into what has happened at Telmex since that date and how we are influencing the day-to-day improvements in Telmex.

First a few words about how Southwestern Bell is functioning in Mexico.

+ Southwestern Bell and our consortium partners intend for the day-to-day operations of Telmex to continue being managed by Telmex employees. However, each of the consortium partners is specialized in different areas, serving as advisers and technical experts for Telmex.

+ Southwestern Bell has a core team of 21 employees who have moved to Mexico City to work with Telmex on various key functions. Those include telephone network maintenance, business office procedures, customer service, billing, operator services, procurement, cellular service and directories. Other Southwestern Bell employees are called in as needed to help on specific projects.

+ We are working with Telmex employees on plans for converting older switching offices to digital through a "flashcut", so that customers' phone numbers do not change and their service is interrupted only briefly when an outdated switching office is replaced. The first switching office "flash-cut" will be conducted during the first quarter of 1992.

+ We are assisting Telmex employees in finding and repairing problem areas in switching offices that cause poor transmission on phone calls. There is a lot of trunk blockage between central offices. We've been working on mechanized programs that identify trunk and switching office problems, and we plan to test all cross-bar offices in Mexico City during the next six months.

+ Southwestern Bell people are training Telmex employees in conducting three-way checks to verify that billing, outside plant and central office records are all correct. We've found a 40 percent error rate in the records. Ten percent of the pairs shown to be working are actually vacant and could be assigned. That's 500,000 pairs nationwide.

+ We are assisting Telmex employees in mechanized trouble testing at repair centers and improving repair technician productivity through additional training and supervision.

+ We are showing Telmex how to improve the company's force management and cable management plans. Telmex employees have toured our facilities in Houston to give them an overview of how the Houston network is managed.

+ We have on-site supervisors that are working with Telmex supervisors and employees who are "rehabbing" telephone cables in the Matamoros area. Matamoros has had high trouble report rates, particularly during the rainy season. We're testing products new to Telmex, such as jelly filled cable and new distribution boxes that can withstand environmental problems.

+ We are designing, with Telmex personnel, a new, integrated billing system. Recently, we "captured" all billing complaints from a representative business office. From that, we identified several action items that will improve billing in the short term. In the meantime, we're continuing to work on our long-term project of completely overhauling Telmex's billing system. The integrated billing system will combine permanent customer records with billing information and customers' facility identification records.

+ We have helped Telmex in reorganizing their procurement operations, which are being centralized into one group. The number of warehouses will be reduced from 104 to four and inventory will be reduced from $300 million to $50 million.

+ Our Yellow Pages operations experts are working side by side with Telmex personnel in revamping their Yellow Pages operations. Telmex has implemented a three-year business plan that calls for complete mechanization of the Yellow Pages operation, doubling their sales force, changing work rules and increasing employees' supervision and training. The ultimate goal is of course to significantly increase revenues and profit from this undeveloped part of the business.

+ Our cellular engineering, marketing and operations people are engaged in training Telcel personnel in all phases of this line of business. Engineering has strategically located new cells in Mexico City, in order to improve the quality and capacity of cellular service. Our marketing people have opened many new distribution channels throughout the city and country. In six months, Telcel doubled both the number of cells and number of customers in Mexico City. Similarly impressive results are evident in other locations. Operations people are working to improve the billing system and the interface for billing between Telcel and Telmex.

While I have just mentioned some of the improvements in the cellular subsidiary of Telmex, next, I want to get into specific improvements that have occurred and will occur in the next few years throughout the company. These changes and plans for change have been implemented since 1 January 1991.

+ Telephone service has been expanded to 1,000 villages that didn't have service before.

+ A growing number of Telmex business offices are now issuing service orders with specific due dates (and they are being met). As of 1 November 1991, this included business offices in Puebla, Monterrey and Mixcoac. By 25 November 1991 it included business offices in Hermosillo, Queretaro, Morelia and Veracruz. In December, business offices in Merida, Chihuahua, Guadalajara, Linda Vista and Ermita were brought on line. (By the end of 1992, we hope to have the entire company on due dates.)

+ A growing number of business offices are conducting business by telephone, so that customers don't have to stand in long lines to carry out the simplest business transaction. Also, research is being conducted to determine ways to improve customer satisfaction. In Mexico City, phone contacts at business offices increased from 2 percent to 45 percent in just three months. (By the end of 1992, we plan to have the majority of customer inquiries conducted over the phone.)

Next, I will detail plans for the approaching years to meet governmental objectives and bring Telmex into the "world-class" category of communications networks.

+ Telmex will spend about $2.5 billion per year or $10-12 billion during the next five years to expand and improve its network and services.

+ Access line growth will average 12% per year during the next five years. We plan to reach 7.5 million in 1993 and 16 million in 2000. There are currently 5.4 million lines.

+ During 1991-93:
  * 8,000 rural towns will receive phone service
  * 750,000 access lines will be added.
  * 100,000 public phones will be installed
  * 13,500 kilometer fiber-optic cable backbone will be installed throughout Mexico for long distance service.
  * Digitalization in switching plant will increase from 29 to 60 percent.

+ Central offices serving 500,000 customers in Mexico City will be converted to the latest digital switching technology beginning in early 1992. Our goal is to have 100 percent digital switching in Mexico City by 1995; in Monterrey, Guadalajara and Puebla by 1996; and throughout Mexico by 2000.

+ Telmex will be converting every Telmex operator position to Northern Telecom's TOPS (Traffic Operator Position Systems) switches by the beginning of 1993. Today's 106 operator locations, which all use cordboards, will be converted to 10 state-of-the-art TOPS switches in 33 locations. The first two TOPS switches will be installed in the first quarter, 1992. .mb6.fm2

Under the mechanized TOPS system, Telmex operators will no longer need to manually fill out toll tickets, which have numbered more than eight million per month. Within one or two years after the mechanized toll operator positions are installed, Telmex hopes to begin implementing Directory Assistance.

Finally, a few words about Southwestern Bell's opinion concerning our involvement in Telmex after one year. Are we happy with our investment? We currently own a ten percent equity interest in the company representing an investment of $953 million. As this is being written, less than one year after closing the transaction, that investment is worth approximately $2.1 billion. I'll let you draw your own conclusions concerning our happiness! Would we do it again? ABSOLUTELY!

What has been done since 1 January 1991 is laying the foundation for the more visible improvements to come. To bring Telmex into the "world-class" categories of telecommunications companies will take the five years in the current plans. The people of Mexico expect it and deserve it. It is, therefore, Southwestern Bell's goal, as well as that of our partners, to develop Teléfonos de México into such a world-class telecommunications system, that it will provide a strong foundation for continued economic growth in Mexico.

Pacific Rim Telecom Status Report:
Privatization and Competition Strategies in Mexico and the Lands Down Under

"The Promise and the Challenge"

David Frost
Vice President, Bell Atlantic International
Arlington, Virginia

ABSTRACT:

Driven by the need to extend basic service coverage to support economic and social development., countries are not only modernizing their telephone networks but coming to believe that privately-owned telephone companies, not governments, are best positioned to develop and expand the telecommunications infrastructure. Bell Atlantic International Inc., a co-owner of Telecom Corporation of New Zealand, has been consultants, software and systems integrators for leading telephone administrations, partners in cellular consortia and joint ventures for infrastructure development. It is Bell Atlantic International's belief that while privatization and competition offer enormous promise, it can be an unfulfilled future if certain challenges are not met.

The forces that brought about telecommunications deregulation in the United States over the last two decades -- and the dramatic industry restructuring that led to the formation of Bell Atlantic Corporation -- now are creating the same kinds of changes in telecommunications sectors around the world.

Among those forces are: advances in technology; the need for modern telecommunications infrastructures that can support economic growth and strengtrhen a nation's ability to compete in world markets; and the demand for a wide variety of information services.

These information services can range from basic telephone service to assist in broad social and economic development to new, sophisticated services required by multi-national business organizations.

Nowhere are these forces and the resulting changes more evident than in the nations of the Asia Pacific region. Together, they account for nearly one-third of the global population and contain some of the fastest growing economies in the world.

Prompted by the increasing importance to their respective economies of advanced telecommunications systems, Indonesia, Taiwan, South Korea, Singapore, Hong Kong, Malaysia, New Zealand, Australia and Japan together are expected to spend over US$100 billion on telecommunications development in the mid-1990s.

Bell Atlantic's strategy -- to become a leading worldwide provider of telecommunications and information management services -- complements the national telecommunications strategies of many Asia Pacific nations.

Bell Atlantic seeks to achieve this objective by participating in international ventures that capitalize on strengths we have developed in the United States.

Bell Atlantic serves the telecommunications needs of the eastern region of the United States, an area containing nearly 34 million people in 13 million households, along with 845,000 small business customers.

The capital of the United States, Washington, D.C. is situated in the heart of Bell Atlantic's territory. Among the corporation's biggest and most advanced customers are the U.S. Federal Government, including the White House and Congress, as well as the embassies of many nations from around the world.

Bell Atlantic also serves some of the most sophisticated, communications-intensive companies in the United States. The headquarters of 62 of the nation's Fortune 500 Services companies and 80 of the Fortune 500 Industrial companies are located within Bell Atlantic's territory.

The Bell Atlantic telecommunications network is one of the most advanced, well-managed and cost-efficient landline telecommunications systems in the world. Residential, business, government and diplomatic customers rely on a wide range of telecommunications services provided by Bell Atlantic's seven telephone companies, which serve over 17 -and-a-half million telephone access lines.

With the acquisition of Metro Mobile CTS, Inc., Bell Atlantic will be one of the largest cellular telephone carriers in the United States, with nearly a half-million customers.

In addition to providing landline and wireless communications systems, Bell Atlantic also offers state-of-the-art business systems capabilities that help many of its customers extract the maximum financial and operational values from information technology.

Bell Atlantic is parent to several organizations that provide computer services and support, systems integration; expert systems connectivity and network management software; information and communications systems, software and supplies; and a broad range of equipment leasing and financial services in regional and national markets.

Outside the U.S., it is Bell Atlantic International's responsibility to actively market our core telephone business and related skills and technologies.

We also explore investment opportunities that will help us reach our strategic goal of becoming a leading international communications and information management company.

In the process, we've been consultants, software and systems integrators for leading telephone administrations around the world.

We are also partners in several ventures around the world that are modernizing telephone networks, constructing national cellular systems and building public packet-switched data networks.

Bell Atlantic is a member of the consortium that purchased New Zealand's state-owned telephone company. Valued at US$2.4 billion, half of which was invested by Bell Atlantic, this was the largest telecommunications acquisition in Asia/Pacific history.

The logic of our investment was confirmed quite dramatically in July by the overwhelmingly positive response in world markets to the initial public offering of Telecom stock. The demand for shares was extremely high.

Out of the sale, Bell Atlantic realized a one-time gain of about $75 million, which we are using to support long-term financial initiatives, such as capital recovery, restructuring and further business development.

New Zealand Telecom's performance has exceeded our expectations. With this first big offering out of the way, we're working even harder on developing synergies with Telecom, particularly in the new product and business development areas.

We've also been eager to explore additional investment opportunities in New Zealand that complement our basic business strengths.

Last May, for example, we teamed up with Ameritech and the two top cable TV system operators -- TCI and Time Warner -- to purchase a 51 percent interest in Sky Entertainment Television, which provides multichannel pay television services in New Zealand that can be successfully developed.

In Czechoslovakia, we are partners with US WEST and the Czech and Slovak republics in a joint venture called, "Eurotel." In September 1991, Eurotel marked a major milestone, placing the first call on Eurotel Cellular Service just 10 months after beginning the joint venture.

Eurotel's present capacity is 4,000 customers, and that will grow to more than 11,000 customers by the end of 1992. By the end of 1991, Eurotel also will offer packet data network services.

Eurotel represents a ground-floor opportunity in a country that urgently needs a modern communications infrastructure.

Elsewhere in July 1991, we announced that International Computers Limited had become part-owner of Bell Atlantic Customer Services International, whose companies provide computer maintenance services in Western Europe. We view this partnership as an ideal opportunity to support our business growth plans while providing customers with a more varied and rich portfolio of services to meet their business needs.

In a nutshell, our international strategy is characterized by an in-depth focus on prime markets and multiple opportunities that allow us to do what we do best -- add value to communications networks. We intend to be selective, targeted and smart., especially when it comes to long-term investment.

We view today's international marketplace as the opportunity of a lifetime. Driven by the need to extend basic service coverage to support economic and social development., countries are not only modernizing their telephone networks but are coming to believe that privately-owned telephone companies, not governments, are best positioned to develop and expand the telecommunications infrastructure.

Telecom privatization and competition offers enormous promise to a nation. It can attract additional financial, technical and managerial resources to the country.

In addition, by allowing commercially minded firms to participate in telecommunications, there could be an improved responsiveness toward customers and expanded coverage of telecommunications services. The efficiency of the workforce and network would also improve and prices for services would be brought in line to benefit all customers.

Other potential benefits include: expanding the availability of the types and geographical reach of new services; maintaining and expanding the asset value of the company; removing the day-to-day operation of the company from the national political process; reducing financial demands on the national budget; accelerating innovation and capital investment in the telephone network; and improving the quality of life of a nation's citizens.

In developing countries, they are also realizing that a modern telecommunications infrastructure is necessary not only for domestic economic growth, but also to be able to compete in world markets and attract foreign investment.

As a result, the privatization of the telecommunications infrastructure should be viewed as a vehicle to enhance economic development. As service improves, so will the business community's telephone usage and productivity.

But for all the promise that privatization and competition offers, there are also enormous challenges.

For companies, like Bell Atlantic, the challenge is to select wisely from the range of investment opportunities available today and in the near future.

Today, we know of nearly 30 telecom privatizations underway or under study in nearly every corner of the globe. It is widely agreed that there are more telecom investment opportunities today than there is global investment capacity to deal with them. And we believe that trend will continue.

There are some important considerations that influence the level of interest and competition in a privatization.

First is the amount of opportunity that exists to add value to the investment in growing revenues. This includes such things as:

- The country's economy -- as it is today and as it likely could be based on political and economic changes.
- The overall environment surrounding the privatization.
- The country's tax structure, limitations on foreign ownership, and dividend treatment.
- The degree of pricing freedom or regulation.
- The opportunity to improve existing products and introduce new ones.

There are also purchase considerations, such as: having the right partners; currency stability; acquisition expenses; requirements to sell down and opportunities to sell shares; financing arrangements; size of the company; and all the legal matters, such as property titles, liabilities and warranties.

For example, getting the very favourable conditions that attracted us to New Zealand was in itself an important and well negotiated. Access to company and the freedom to manage it.

Our decision to invest in New Zealand Telecom is also based on a number of other factors that will contribute, over an opportunity for profitable business expansion for Bell Atlantic and increased shareholder value.

And the absence of rate of return regulation meant that cost reductions and revenue stimulation directly affected the bottom line.

Making a profit on a temporary investment in New Zealand was never our primary objective, but rather the value for Bell Atlantic was in making a permanent, ongoing investment in New Zealand Telecom.

For governments, the challenge is to do what New Zealand did. And that is to create the right conditions and climate for privatisation.

Privatisation alternatives range from:

- The government hiring private individuals or companies as consultants and contract managers.
- Sharing profits with a foreign telephone company to manage the system.
- Selling part ownership of a company to raise capital.
- Selling controlling interest and management responsibility for the company to a foreign operator while retaining partial ownership for the benefit of employees and other domestic interests.

Many privatisations now in the planning stages involve companies that already have been "corporatised" or pushed away from the post office or the ministry to begin operating like a private sector company. New Zealand Telecom was "corporatised" about two years before it was privatised.

Related to privatisations - but stopping well short - are projects of private undertakings where telephone administrations have formed ventures with the private sector to accelerate the deployment and development of sensitive or critical telephone infrastructures.

Whatever the alternative, companies like Bell Atlantic are more ready to participate and to complete agreements which benefit governments and investors the right set of conditions that will improve the value of the asset.

Another important challenge is that selling a valuable national asset like a telephone system is an emotional issue. It is critical for foreign governments to have clear objectives.

The government must be realistic about the value of the asset and understand the motivations and future expectations of the buyers, as well as key opinion formers in the country including customers, unions, political supporters and opposition.

The temptation is to sell the property to the highest bidder without regard to the technical and service proficiency or other intrinsic values of the enterprise. The short-term profit gained, no matter how high, will not short the positive and potential benefits of privatisation.

A recent article in Business Week put it succinctly:

"Selling off state assets has to disruption and is no sure investment. It means that secure jobs are destroyed and confidence but inefficient practices are entrenched. But there will much choice anymore. Countries hanging out the 'For Sale' sign have a common set of needs to mobilise domestic savings, get foreign cash into their economies and create jobs."

The first - and perhaps biggest challenge for owners, customers and public policy makers alike is to turn the promise of privatisation, competition and emerging information technology into a strategic competitive advantage that benefits the company, its customers and the country.

TABLE # 1 - SUMMARY OF MAJOR INVESTMENT BY REGION

Region	Invest 1990 $ bill	Popul. 1989 (million)	Average* Annual Growth in %(lines)	Subscriber Line(1989) (million)	Relation Line/100
Europe	43.0	685.4	5.7	195.9	23.4
N America*	30.0	340.0	2.9	143.6	52.7
Asia Pac Rim	28.0	3,156.3	6.0	105.0	3.3
L America	6.0	372.5	7.2	25.0	6.7
Total	107.0	4,554.2	5.0	469.5	10.3
TOTAL World	125.0	5,192.0	5.0	476.0	9.2

* Average between 1979 -1989
Note:1: Asia Pac Rim data include Asia and Oceania
2 North America include only Canada and U.S.
3 Latin America include Mexico and Caribbean and South America
source: The World Bank Annual Report(1989), Siemens International Telecom Statistic (1990), World Statistics United Nations (1988).

this include equipment, training and services. The world Telecommunication sector invested U.S.$ 116.0 billion in this sector in 1989 with an annual growth of 7.7% .

Perspective of the market: (1990/1996)

Total investment estimated is U.S.$ 927 billion.
Expansion of Subscriber access terminal is estimated in 170 million
1989 total subscriber access terminal: 476.3 million

Worldwide, there are a total of 476.3 million installed telephone lines, the average annual growth of telephone lines between 1979 and 1989 was 5.0%. The average number of telephone lines per 100 inhabitants in 1989 was 9.3.

5. The Telecommunications global market in the 90's

This marketing study focus in the nine major investment countries which are planning to invest major resources in the Public Telecommunications infrastructure during the next six years in the major regions of the world: Latin America, Europe and Asia Pacific Rim.

The countries by each region covered in this study was chosen not only as a major investor in Telecommunications in each region, but the potential in long term to growth in Equipment and services environment. The countries by region studied in details for this study is listed below:

Latin America: Brazil and Mexico

Europe: France, Italy and West Germany

Asia Pacific Rim: Australia, Japan, South Korea and Taiwan

note:The North American market are not covered in this specific study.

The table #1 summarize the major data of each region in the world covered in this study that are investing in Telecommunications by population, Per capita GNP and subscriber line. The Telecommunication networks with the liberalization factor in the worldwide market is gathering pace, spawning the introduction of new services and technologies.

The deregulation of phone markets has already lead to a partial globalization of the industry. Network operators in countries where the markets have already been deregulated, principally AT&T and the baby Bells in the U.S., British Telecom and Spain's Telefonica, have started to broaden their branch and expand overseas.

This diversification has been promoted partly by a feeling that their prompted partly by a felling that their opportunities for growth at home were limited by a desire on the part of regulators to reduce their market shares. It has also been prompted by a perception that international markets were full of opportunities.

6. The third wave of communication technology

Computing and Telecommunications are converging at least because information technology promises to become cheaper and thus more widely used. It is now worth building networks to gather and process data which earlier would have been paper bound or left uncollected.

This technologies are converging so suddenly because old monopolies have been broken. Competition has stormed through the telecommunications industry, and the rout is not over. Mr. Harold Green, the American Judge, broke up AT&T into a long distance carrier and seven regional telephone companies in 1984. By that time technology,

particularly satellite and microwave communications, had frustrated arguments for a natural monopoly in making distant connections. Likewise, the technology of mobile telephony is now undermining the arguments for a natural monopoly in local telecommunications. Moreover, the assumption that only a monopoly could afford the vast investment needed to build a country's network was outdated: a nationwide network was already in place.

Another concept called the intelligent network will sweep through telecommunications toward the end of the century. The equipment form which the intelligent network will be made abide by a universal standard. This means that many equipment makers will make products for it. The telephone companies will thus have a choice of suppliers.

The intelligent network separates features from switching. The features are programed into a normal computer which sits beside the network. Whenever a service is needed, the network fetches it from the computer and acts accordingly. This give the carriers at least two advantages. First, anyone can write the software for a new service since it will be running on a conventional computer. Second, only a few computers, need be on the network, which makes it cheaper to set up. This attract carriers because it allow them rapidly and cheaply to introduce new services, such as dial-up films or special telephone networks which are dedicated to a given subscribers.

The consequence of the intelligent network will be a fearful battle between switch makers and computer makers over the boundary between services that are switch based (those like call waiting, that are more popular) and services that are computer based (Voice Mail and other value added services). Even an electronics company that has both telecoms and computing outfits under its roof is likely to find that an old telecoms contract is passed on to a rival computer maker.

7. Major Market Trends

The major markets for telecommunications worldwide continue to be the largest buyer of telecommunications equipment, as North America, Europe, and the Asian Pacific Rim region.

The only significant growth is investment in long erm is likely to occur outside this region. Historically the trends confirm our estimative as you see in the table below:

Growth of main Lines per continent(1979/1989):

Region	Growth (%)*
Latin America	7.2
Asia Pacific Rim	6.0
Europe	5.7
North America	2.9
Worldwide	5.0

* Mean annual growth in % per annum
source: International Telecom Statistic - Siemens 1990

As a summary of the three regions covered in this study we present a total investment during the period of 1986 to 1996 for Latin America, Europe, and Asia Pacific Rim.

In Latin America, Europe, and Asia Pacific Rim regions, there are a total of 325.9 million installed telephone lines, the average annual growth of telephone lines between 1979 and 1989 was 4.9%. The average number of telephone lines per 100 inhabitants in 1989 was 7.7.

The Latin America, Europe, and Asia Pacific Rim region projected growth for the period of 1990 to 1996 is shown in the table below:

YEAR	Subscriber Terminal (million)	Investment (billion dollar)	Population (million)
86	273.8	55.5	4,022
87	289.6	59.4	4,083
88	306.8	69.0	4,143
89	325.9	75.0	4,206
90	345.0	82.0	4,269
91	367.5	89.3	4,325
92	391.0	96.0	4,388
93	414.5	103.7	4,440
94	440.0	112.3	4,492
95	465.0	121.0	4,541
96	493.0	129.8	4,593

8. Global Strategies in the Telecommunications Sector

The strategies in the 90's will be focus in the competition of telecommunications industry. To understand the traditional structure of the world's structure of the telecommunications environment is important to highlight some facts.

Historically, the majority of governments, except Canada and the U.S., have been encharged the provision of telecommunications services to a national monopoly. Telephone service was usually combined with postal and telegraph service in a government Postal, Telegraph and Telephone Administration, or PTT (Postal Telephone and Telegraph model).

In the majority of industrialized countries, the PTT procurement were directed to the growth of domestic telecommunications equipment manufacturing. The status of Telecommunications monopoly was preserved and recognized by most of the industrialized countries, and protected from any kind of foreign competition. This fact was unique from almost all other industries, and its special status is reflect today in the fact the most nations do not subject their PTTs to Government Procurement Code of GATT.

Monopoly service providers have little incentive to reduce costs or improve services. Ultimately, it is the consumer who must bear the burden of unnecessary high costs while being deprived of new products and services.

The major force for change in the U.S.A. has been competition, leading to liberalization, deregulation, and ultimately, the AT&T divestiture. Beginning with the liberalization of CPE policies in the late sixties and culminating with the divestiture of AT&T of its local operating companies, the U.S. government effectively opened both the equipment and service sectors for the U.S. Telecommunications industry to competition.

A driving force behind the procompetitive policy was the demand of network users for lower transmission costs and a large variety of equipment and services. The development of computer and the information society in the U.S.A. gave rise to increased demand for electronic information services in a wide variety of industries.

The effect of the liberalization in the U.S.A. have drawn-out to the International Telecommunications environment. The increased penetration of the U.S. market by international companies to see access in the largest market in the world in absolute value, has undertaken the U.S. Government to a number of initiatives to encourage foreign governments to remove Telecommunications market barriers, further straining the traditional market structure.

Technology is also a major contributing factor in the rise of global competition in the Telecommunication sector. The increasing integration of computer and telecommunications technologies has pushed a trend toward mergers, acquisitions, and cooperative agreement in the international Telecommunications suppliers environment.

9. Markets of The 1990's

The Telecommunications market in the 90's and beyond will be in a fast pace, with the industry cycle of the new products shorten as soon the competition pushing towards quality, price and time delivery factors.

The deregulation of Telecommunications market has already lead to a partial globalisation of the industry. Countries which have not embarked in this liberalization stage, it is becoming common to open the market for data and mobile communications which are its fastest growing sector.

Telecommunications market trends have been influenced in several ways by the technology of digitalization, trough the availability of satellite services, fiber optics and broadband availability. New technologies are more reliable and faster, offering a wide compatibility for applications of voice, video and data in the same circuit. ISDN the Integrated Service Digital Network will be one of the major services available for the International Business community in the major developed Telecommunications country.

The ISDN evolution currently in the international telecommunications environment establish at 144 Kbps in two 64 Kbps D-channels and one 16 Kbps channel to carry encoded voice and data.

10. Deregulation Worldwide

The Telecommunications policies of state governments worldwide and multilateral organizations have an important effect on the performance and ultimate competitiveness of the Telecommunications industry.

The escalation pace of technological innovation and steadily increasing development costs, combined with increased competition in the U.S. marketplace from International Telecommunications suppliers, are leading to additional pressures and incentives for U.S. companies to move into the international arena.

While the United States procompetion style have gained some acceptance abroad over the past five years, there remain substantial differences in the progress of deregulation from one country to another. These lead to a significant variance in market accessment for International Telecommunications equipment suppliers and services in the global market.

11. Conclusion

This study show that the Long Term trends of the largest growing market in the Public telecommunications worldwide investments would be Latin America. The Region are expected to invest more than U.S.$ 62 million representing a growth average of 24 percent and expansion of the access terminal 13% a year in average.

In absolute values the Europe and Asia Pacific Rim are the top region in the world surpassing United states in average growth respectively 14 and 5 percent in investment in the public telecommunications infrastructure.

In term of absolute value of terminal access expansion Europe long term trends are very satisfactory, with the inclusion of Eastern Europe in the market the number may increase more than we projected that is around 69 million new terminals for the period.

This market will be very competitive with the growing deregulation in the worldwide market. Price, technology, quality and service will be the key factors for suppliers of telecommunications equipment became a major player in this challenge Global Telecommunications environment.

Global Telecommunications Standardization and Regionalism

Meheroo Jussawalla
Institute of Culture and Communication, East-West Center
Honolulu, Hawaii 96822 USA

David Lassner
Office of Information Technology, University of Hawaii
Honolulu, Hawaii 96822 USA

1. Abstract

Global telecommunications standardization activities used to be an activity primarily indulged in by public telecommunications operators to allow basic interconnectivity of voice systems. Technological advancement and increasing deregulation and liberalization of telecommunications in the developed world have altered global standardization efforts through increasing domination by transnational telecommunications interests focusing on advanced digital services. Perhaps the most important structural change in the global telecommunications standardization regime is the regionalization of standards creation with major new initiatives in Europe, the United States, and Japan. Regionalism may also be a key for non-participants in the standardization processes to assure their input is considered.

2. Introduction

In an age of exploding multimedia dependent on digitization, all of the media become translatable into each other. Component bits migrate and any message, sound or image may be edited from one medium of transmission to another. This is the basis of interconnectivity. In turn these developments create an economic interdependence among producers, distributors and users of common facilities. The policy goals that define and constrain their relationships are of importance to society.

In order for government to provide for effective use of new communications technologies, it must promote standard setting processes. This is because new technologies create new communication pathways that need new gatekeepers to mediate dialogue. The most significant issue that emerges from these "technologies of freedom", as Ithiel de Sola Pool has defined them, is the concept of universal service. With the diversity of value added networks, the question arises of what constitutes universal service in an information age. For example, the growing use of PBXs and high speed data transmission for private business networks may drain the resources available to public switched networks. In such a framework the interoperability of the infrastructure itself depends on the availability of standards. The pricing system of new technologies like ISDN is heavily dependent on the acceptance of standards, without which vendors will be reluctant to enter the market. With the new freedom the RBOCs in the U.S. have gained to provide information without having to create separate subsidiaries [1] the distinctions among hardware, software and the network are disappearing. Most new technology is software driven and software defined, making future systems more flexible.

3. Background on Standards

Two of the most important worldwide trends driving economic, political, and social policy are the emergence of the information age and increasing internationalization. Global telecommunications standards are a crucial underpinning of these trends as they develop separately and as, together, they enable the emergence of the global village.

In just 20 years the international network has evolved from requiring human assistance for a voice call between most international points, to allowing unattended facsimile and data transmissions throughout most of the developed world. Global networks permit transnational corporations to operate internationally with most of the same capabilities that are available among sites in their home country (albeit with higher costs). And Integrated Services Digital Networks (ISDNs) may soon deliver the the capability for advanced network services to homes throughout the developed world.

This is all possible only through the development and adherence to standards; in this case agreements on how information technology devices communicate with each other. There is a growing body of literature on the economics of standards [2,3,4] in which the advantages, disadvantages, and processes are considered.

3.1 Incentives and Disincentives for Standardization

Ideally standards might be developed purely within the marketplace. However in many cases there may simply not be adequate incentive for individual players to develop or adopt standards, even when there are significant benefits to be obtained. As a matter of public policy then, government may mandate some level of standardization.

3.1.1 User Perspective

Users of information and telecommunications systems are widely considered to be major beneficiaries of open standards. Following are some of the key benefits of standardization for users:

- *Interoperability*
  Connectivity with large numbers of compatibly equipped other users provides significant externalities, e.g., for users of telephones, facsimile machines, and dialup modems.

- *Decreased costs*
  Standardization permits economies of scale in production, for example, by making mass production of specialized chip sets economical. Furthermore, the presence of multiple vendors of standard products in the marketplace generally leads to more competitive pricing and lower costs than in single-source markets.

- *Vendor independence*
  Users perceive value in the increased flexibility and decreased risk associated with portable applications; they need not be tied to the fortunes and practices of a single vendor.

- *Stable infrastructure*
  Standardization creates platforms on which advanced development may take place. For example, the emergence of the IBM PC bus as a standard enabled the development of a wide range of add-in boards with advanced functions that were not available on previous systems with smaller shares of the market.

Users may also be concerned about possible negative effects of standardization. These include:

- *Manipulation of standardization*
  Users worry that powerful vendors may use standardization as an anti-competitive tool by legitimizing proprietary technologies, resisting improvements, and switching standards at times that benefit their own competitive position.

- *Stifling of innovation*
  Adoption of standards may make it difficult or impossible to migrate to superior technologies as they become available. Use of the QWERTY keyboard layout, even in the face of proven superior alternatives such as the Dvorak keyboard, is an excellent example of this inertia effect.

3.1.2 Vendor Perspective

Vendors, on the other hand, may see open standards in a different light. Proprietary technologies, as opposed to open standards, may be used to exploit competitive advantage by providing vendors with:

- *Captive markets*
  IBM established and maintained its domination of the data processing marketplace through a complex set of proprietary systems that locked in users to IBM technology.

- *Advanced services*
  Standards nearly always lag behind the most advanced technologies. Non-adherence to standards frees vendors to take advantage of the latest developments in its product line, offering more advanced applications and products to users willing to purchase before the establishment of standards in new areas.

At the same time, vendors see that adherence to industry-wide standards can provide them with market advantages due to:

- *Increased interoperability*
  It is, of course, easier to sell a telecommunications product that interoperates with other vendors' equipment, particularly for a new vendor entering the market. This follows from users' general preference for standardized systems.

- *Expanded markets*
  Adherence to standards can increase the scope of a vendor's market. All users of the standard system are potential customers. In markets without standards a vendor may only be able to sell to customers who have selected their particular version of a technology. This is particularly the case in international markets, in which large vendors perceive adherence to global standards as a key to becoming viable suppliers in other countries.

- *Market leadership*
  Given users' generally positive perception of standards, a vendor that is an early adherent to a standard can capture early adopters of a new technology as customers. At the same time this enhances the vendor's image as a technological leader.

- *Stable infrastructure*
  Standardization can create many new market opportunities by providing a viable base for the enhancement of standard products.

3.2 Theory of Standardization in the Marketplace

In the marketplace, even in situations in which everyone benefits from adoption of a universal standard, it is possible that no such standard will emerge. And if standardization does occur, there is no guarantee that the best standard will be adopted. This is because there are many players with different interests and concerns. Standards can be an important aspect of the market's landscape, and each player may have tremendous incentives to either block standardization altogether or to insist on adoption of their own technology as the only acceptable standard. The success of standardization efforts will then depend on whether the perceived benefits of overall standardization outweigh each players' insistence on their own positions. If so, compromise may be possible which can facilitate a standardization process in which the entire marketplace realizes a net benefit. Otherwise, in situations in which there is an overriding public good to be fulfilled through standardization, government may have to step in and mandate standardization if it is to occur.

3.3 Standardization and Public Networks

The politics of network planning in Europe differs from the network fragmentation theory in the United States. The differences in political implementation far outweigh the structural similarities in the choice of technology for economic progress [5]. In Europe, the planning process for common standards is part of the political scheme for European integration. These decisions are grounded in economic theory. Economic efficiency and economies of scale imply an organizational solution to the problem of developing international standards. Public networks would ideally serve as a collective good for which stable user-network interfaces, OSI interoperability, integration and flexibility through easily programmable software are desirable technical features. But how the new infrastructure is implemented in the U.S. and Europe will ultimately depend on the political institutions that will implement these tasks.

From a global perspective, attempts at standardization have so far failed to reconcile the long-term need for digital infrastructure integration with the short-term need for specialized networks under decentralized ownership and user control. The theoretical argument is based on the movement from national public service requirements to a critical industry with a world market of $800 billion growing at 7% a year. The hypothesis is that competition rather than central planning of this high technology sector

will achieve greater economies of network integration than the natural monopoly generated economies of scale and scope. The rules of the game have changed so that hybrid distribution systems offer product differentiation to users of information services. These developments have challenged the traditional criteria of high costs and resource scarcity whereby unified access to the telecommunications system was mandatory. Without standardization and network integration, carriers cannot justify the high cost of providing broadband fiber-based access to the home.

4. Traditional Standardization Processes

International standards have traditionally been set by global standards organizations. International standards often describe interconnectivity of systems, leaving some details of user connectivity to be determined on a national or regional basis.

4.1 International Standards Bodies

Traditional standards bodies have a variety of backgrounds and focus on different areas. There are both treaty and voluntary bodies at both the international level and national levels, and regional bodies have been active in Europe. A major common thread in all telecommunications standardization has been the dominant role of the Public Telecommunications Operators (PTOs) and their preferred equipment suppliers. Usually the PTO has been a government entity (in most countries a PTT) and sometimes a regulated monopoly (e.g. AT&T in the U.S.). The preferred equipment supplier has likely been a national monopoly or the PTO itself.

4.1.1 International Telecommunications Union (ITU)

The International Telecommunications Union (ITU) is a treaty organization which specializes in telecommunications. Although it now operates under the auspices of the United Nations, the beginnings of the ITU go back to the mid 1800s and the development of the international telegraph network. Formal membership is restricted to governments, and most nations of the world retain membership. Standardization activities occur in two permanent bodies within the ITU: the International Telegraph and Telephone Consultative Committee (CCITT) and International Radio Consultative Committee (CCIR). The CCIR is primarily responsible for transmissions that occur through radio transmission, while CCITT is responsible for wired telecommunications standards. In practice there is increasing overlap between these two areas, particularly with the increasing use of digital transmission systems, and the two consultative committees work closely together when appropriate. Most of the actual standards work in the CCIs is done by private sector entities that are identified as Recognized Private Operating Agencies (RPOAs) or Scientific and Industrial Organizations (SIOs) by their governments.

4.1.2 ISO-IEC

The International Organization for Standardization (ISO) is an international voluntary body that promotes and facilitates standardization. Its membership is the national standards organization for each country, which may or may not be a government entity. A separate body, the International Electrotechnical Commission (IEC), is responsible for electrical and electronic standardization; all other areas fall into the purview of ISO. Together, ISO and IEC have formed a Joint Technical Committee 1 (JTC1) with overall responsibility for information technology standardization.

ISO and the ITU are headquartered across the street from each other in Geneva. Typically telecommunications standardization has been left to the ITU CCIs, and information system standardization has been handled by ISO. There is, of course, significant overlap between these two areas and the two groups work closely to avoid unnecessary duplication of effort. For example, in the crucial area of Open Systems Interconnect (OSI), many of the key standards are identical.

4.2 Typical Standards-Making Processes

Standards-making processes vary according the organization developing the standards, the nature of the standard itself, and the state of development of the particular technology in question. A typical process begins with the decision, generally made at the highest level of the standards organization, that a standard is required in a particular area. The task is then assigned to a particular study group or technical committee, usually composed of technical staff from members with an interest in that technology. The technical group works until it reaches consensus. Then the standard is ratified in some fashion back at the highest level of the overall organization. The final product of the process is generally considered to be a recommendation. It only has force of law if a legal authority within a particular country or region mandates use of the recommendation as a required standard.

4.3 Standardization outcomes

Sometimes consensus simply cannot be reached. This may be due to the opposition of one or more powerful participants in the standards process. More likely, however, it is due to an inability to agree on a particular standard for the technology in question. This can occur even when there is overriding benefit to standardization if the participants have strong vested interests in a particular standard or in blocking a particular standard. When, however, a standard is finally recommended, it may be the result of one of the following kinds of processes:

- *Standards construction*
  Standards may be developed from the ground up. This can be a slow, negotiated process, and many compromises may take place along the way. This takes place most often when standardization begins in advance of actual development and deployment, before participants in the standards process have a strong vested interest in promoting or blocking a particular outcome, e.g. their own or a competitor's product respectively. Standardization of Integrated Services Digital Networks (ISDN) is an example of this kind of activity. There are several potential dangers with this kind of early standardization. One is that by standardizing before a product or service is proven in the marketplace, it may turn out that there is little demand by users. Another problem is that standards set in advance of implementation may be technically flawed due to the lack of real-world experience with the technology, and may require significant revision or enhancement.

- *Standards adoption*
  In some cases an existing implementation is accepted as-is as a standard. This may be fast, but it may give

an advantage to the developer whose standard is selected. Competition among various implementations to be recognized as the standard may be fierce, and standardization process participants with no favored implementation may simply wish to block someone else's proposal to avoid yielding competitive advantage.

- *Standards adaptation*
  A new standard may be the result of a process somewhere between the previous two. An existing implementation may be the basis of a negotiated standard, after being adapted in accordance with the demands of other participants. The changes may be required to improve the standard functionally or simply to limit the competitive advantage of the original proposer.

- *Standards with options*
  Sometimes there can be no adaptation or compromise that garners consensus. In that case, some organizations will accept standards with multiple options, where each option corresponds to one of the proposals. This outcome is somewhat more effective than no standardization at all, since it may limit the number of options in the marketplace and permit some of the benefits of standardization.

4.4 Issues in standardization

The traditional process of developing international standards has been widely criticized. This section briefly considers the most common and serious issues raised regarding the process itself.

4.4.1 Slowness and bureaucracy

The formal standards setting process has been considered to be slow and burdened by bureaucracy. Even with new "fast track" procedures in effect [6], beginning a new standardization process after the need is perceived or competing technologies are on the market is too late. Videotex and color television standardization efforts are examples of the problems that occur when entrenched national standards are supported in international fora [7]. With the rapidly accelerating pace of technological advancement, this problem has become even more severe. In a competitive marketplace vendors will simply not wait for standards before developing and deploying new technologies that users need. It is now widely recognized that standardization must be more market-oriented and efficient [8].

4.4.2 Technical quality of negotiated standards

As standards are negotiated, particularly in the political setting of an international forum, technical excellence may be sacrificed to the pragmatic need for agreement and political considerations unrelated to the standard or technology under study [9]. Another problem is that standards developed in advance of implementations may be technically flawed, and require revision as lessons are learned through implementation efforts.

4.4.3 Resource requirements and distribution of costs

Active participation in the standards process is extremely expensive. It is estimated that hundreds of millions of dollars per year are spent on standardization [10]. Lengthy meetings are held in international locations. Perhaps more significant than the travel and lodging costs that must be borne by the participants' employers are the costs associated with the time and salary of these highly valued employees. Some active participants in the standards processes believe that the costs of standards development are unfairly allocated; that while they bear the bulk of the costs, numerous other non-participants have equal rights to develop products in accord with the resultant standards [11]. These non-participants benefit from the research and expense of the standards process without paying any of the costs.

4.4.4 Limited access to standards

The language of standards is sometimes thought to be obtuse; new terminology is often devised, critics claim unnecessarily. The standards have only been available in hard-copy, generally at prices high enough to serve as a deterrent to casual collection and inspection [7]. The ISO clearly states that their publication resale program helps support the organization. The CCITT is now beginning to make its standards freely available on-line [12].

4.4.5 Intellectual property rights

All cooperative standards organizations grapple with the relation of standards to intellectual property rights. Standards are, by intent, intended to be freely available and widely used. But there is the possibility that compliance with a particular standard may require use of a technology (e.g. patent) that is owned by an individual or firm. This would clearly compromise the standard and potentially the standardization process. Most standards organizations ask that participants openly declare their interests in any intellectual property that might be required for compliance with standards under consideration. Participants with such interests must be willing to agree to license their interests on a reasonable and non-discriminatory basis or work on the standard will not proceed. However there still remains the possibility of unintentional non-declaration, malicious non-declaration, or overlap between a standard and some intellectual property right of a non-participant in the standardization process.

4.4.6 Limited participation

Users seldom have the resources to be active players in the standards forums, although organizations such as the International Telecommunications Users Group (INTUG) and the International Chamber of Commerce (ICC) can serve as a voice for users. Similarly, lesser developed nations (LDCs) also lack the resources to actively participate. Non-participants sometimes claim that the scope and/or contents of the standards being developed do not address their needs.

5. Change in Regime

The quickening pace of technological advancement, increasing internationalization of business, and worldwide trends toward deregulation and liberalization of telecommunications have relentlessly spurred the demand for more open and timely global telecommunications standards. The ITU has had to reconsider its basic functions and structure in light of this changing landscape in order to attempt to retain its leadership role or even remain viable [13]. Similarly, the ISO and IEC have reconsidered their standardization processes in the face of fundamental changes in the technological environment

[14]. In this section we briefly describe one of the important changes in the telecommunications standardization regime that is taking place.

5.1 Regionalism

One of the most influential trends in standardization through the mid and late 1980s has been the emergence of what are generally referred to as regional standards organizations (RSOs). These organizations have grown out of the recognition that with the deregulation and liberalization of telecommunication authority, formal national or regional standards are required to ensure interoperability of public telecommunications systems. International telecommunications standards generally do not address all aspects of the system (e.g. the user-network interface) and sometimes leave options from which each country can choose. Therefore some standardization is still required on a more localized basis.

5.1.1 United States - T1

After the divestiture of AT&T in the United States it was clear that there would need to be coordination among the new carriers to assure continuing network integration and interoperability [15]. The Exchange Carriers Standards Association (ECSA) was created to meet this need. With the recognition that carriers alone could not set telecommunications standards, a more broad-based standards committee was formed under the auspices of ECSA. Beginning in early 1984, Committee T1 assumed responsibility for telecommunications standards in the U.S. T1 is made up of representatives of the carriers themselves as well as manufacturers, interexchange carriers, vendors, users, and others with an interest in telecommunications standardization. T1, like the CCITT in the international arena, is responsible for wired telecommunications standards.

5.1.2 Japan - TTC

Japan began deregulation of telecommunications in 1985. As in the U.S., it was recognized that standardization should be primarily a non-governmental activity. The Telecommunications Technology Committee (TTC), similar to T1 in the U.S., was established in late 1985 [16]. TTC has responsibility for standardization of radio as well as wired telecommunications technologies.

5.1.3 Europe - ETSI

The European Conference of Postal and Telecommunications Administrations (CEPT) was traditionally responsible for European telecommunications standards. As part of the impetus to create a single European market by 1992, the issues surrounding telecommunications were carefully studied. A fully integrated telecommunication system was considered crucial both for the role of telecommunications in facilitating the single market as well as due to the size and importance of the telecommunications industry itself (equipment and services). Regional standards to supplement international standards were a clear requirement, so in 1988 the new European Telecommunications Standards Institute (ETSI) was created with responsibility for both radio and wired telecommunications standardization [17]. Unlike T1 and TTC, ETSI includes administrations (governments) and national standards bodies in its membership. It also engages professionals on a for-hire basis to engage in standards development, as opposed to relying on voluntary contributions from the staff of its members.

5.2 New Summitry

The RSOs were not established to supplant the international standardization efforts of organizations like the CCIs. Rather they set standards in areas in which there are no international standards, and establish national or regional profiles in areas where the international standards are incomplete or allow options. However, as they began operation, it became clear that there was tremendous potential for conflict among the RSOs and CCIs, or at the very least for expensive and unnecessary duplication of effort. Furthermore, all the RSOs recognize the importance of global standards, both to assure interoperability of worldwide networks and to facilitate access to worldwide markets by their own telecommunications sectors.

Recognizing the need for coordination, these three RSOs and the CCIs met together at the first Interregional Telecommunications Standards Conference in February 1990 in Fredricksburg Virginia. Generally avoiding the political issues of formal relationships among governmental and non-governmental as well as regional and national organizations, the meeting, which has been dubbed the first "standards summit", was considered a success [18]. A second interregional meeting was held in September 1991 in Nice. The overall outcomes of this summitry so far are:

- Recognition of the preeminence of the CCITT in world-wide telecommunications standardization
- Agreement to continue working together to improve the efficiency and effectiveness of overall standardization efforts
- Agreement to begin using electronic communications technologies to improve interchange among the groups
- Agreement to work toward a coordinated work program and schedule
- Agreement on a number of high priority standards of common interest

The CCITT has agreed to not begin developing standards in areas under active study by the RSOs. The RSOs have agreed to work with each other to attempt to avoid situations in which conflicting and competing proposals are presented to the CCIs. And improved interaction through use of information technologies coupled with a coordinated work and meeting schedule is expected to improve the efficiency and timeliness of the standardization process.

5.3 Industry Alliances

A new trend toward the creation of industry alliances for standardization should also be noted as an important aspect of the landscape. Corporations are increasingly impatient and unwilling to wait for bureaucracies to function, and they recognize the importance of standards if new technologies are to succeed in the marketplace. Very mobile task forces of corporations interested in a particular technology can be formed quickly for specific purposes, allocate resources, and get on with the work while larger and less wieldy organizations are still discussing needs and

process. These industry alliances are often international in nature. It remains to be seen how they will fit in to the new regime.

6. Involvement of LDCs and NICs

Active participation in the global standards-making activities is quite expensive. Participants must attend numerous meetings away from home. And in addition to the costs of travel, housing, and research, the employers or sponsors of the participants lose their time and the benefits of their skills which could be applied to other projects. The result is that a relatively small number of ITU member nations are active participants in standardization. The lesser developed countries (LDCs) and newly industrialized countries (NICs), such as those of Southeast Asia, tend not to have the highly technical human resources required to support highly active involvement in the global standardization activities. And if they do, these are often the people their nations can least afford to do without as they attempt to build their national infrastructures.

One can question whether or not widespread participation in actual standardization activities is important to smaller countries without significant telecommunications manufacturing or export sectors of their own. Just as users believe they need greater input into the process, there is no reason to believe that LDCs and NICs do not share the same sentiment. While on the one hand, some of the grueling technical work of standards-making is really an engineering function, on the other hand many of the decisions on priorities and interfaces have direct impact on policies and infrastructure development.

The new standards summitry has made the long-acknowledged dominance of Europe, Japan and the U.S. more explicit. But the standards proposed by any or all of the RSOs arrive at the ITU as proposals and must still be approved within the appropriate CCI if they are to achieve status as a formal recommendation. It can be argued that this provides non-participants a point of access into the process that might otherwise be altogether unavailable.

Regionalism may be able to play an important role in helping these nations benefit more from global telecommunications standardization. Exercising regional purchasing power and developing regional training and maintenance capabilities can help provide some of the economies of scale available to larger nations. Regional participation in the standards process through shared representatives to important study groups and the establishment of regional positions on key issues may be possible. And development of regional profiles may be useful at times. The key is to find ways in which smaller, less developed nations may be able to improve their ability to benefit from new information technologies and internationalization by providing the sought-after universal access.

7. Conclusion

Today's global standardization activities are being driven by:

- The industrialized nations' needs for the timely development of highly technical standards for the interoperability of complex integrated digital systems;
- The growing influence and needs of transnational interests; and
- The explicit recognition of the increasing importance of work done by regional and national standards organizations in the developed countries.

In the face of rapidly advancing technological development and an increasingly deregulated and liberalized environment, much of the most important and influential standardization activity lies ahead. For much of the developed world narrowband ISDN technology is now available, integrating voice and data. Broadband ISDN is around the corner, promising to integrate video into the network. Development of Intelligent Networks is starting, using ISDN as a building block. Open network regimes in the largest markets are closer, which will open whole new areas to competition. And wireless personal communications networks are one of the fastest new growth areas in telecommunications. Regionalism in the developed world is already changing the telecommunications standardization regime. It may also play a role in bringing the benefits to the rest of the world.

The Potential Impact of Europe 1993 Satellite Policy on Economic Integration in the Pacific Area

Dr. Raymond J. Krommenacker
Counsellor, GATT
Geneva, Switzerland

ABSTRACT

The 1990 Green Paper of the Commission of the European Communities sets the policy goal of the liberalization of satellite services as a cornerstone leading to a single market for satellite communication. After one year, what is the situation with respect to the proposed implementation action plan regarding the earth and space segments as well as the harmonized introduction of the high definition television (HDTV) standard? Are the national regulatory regimes moving faster than the European recommendations? What is the impact on the user, the private operator, the telecommunications organizations and Europe's satellite industry? What are the chances for building a bridge for further economic integration between Europe and the Pacific Area, as a reaction to fractional strategies leading to products and services divided among multiple suppliers?

In November 1990, the EC Green Paper proposed four major changes in the satellite policy of the European Communities: (1) full liberalization of the earth segment, including both receive-only and transmit/receive terminals, (2) free access to space segment capacity, (3) full commercial freedom for space segment providers, including direct marketing satellite capacity to service providers and users, (4) harmonization measures as far as required to facilitate the provisions of Europe-wide services.

In the light of the existing issues, the EC Commission has proposed that a series of actions be taken. In the case of earth segment, these include the following items:

- a text extending the coverage of a directive on the approximation of the laws of the member states concerning telecommunications terminal equipment - including mutual recognition of their conformity, to cover all transmit/receive satellite earth stations, and receive-only satellite earth stations connected to the public switch network;

- a directive for a Community scheme concerning the mutual recognition of licenses for satellite terminal networks, laying down the conditions for the Community-wide operations of such networks, including conditions regulating hub station operation;

- a draft decision aimed at strengthening frequency coordination in the satellite communications field;

- proposals for support measures for the European satellite industry, in particular in the field of satellite terminals;

- acceleration of support for the European standardization programme in the field;

- refocusing of relevant EC research programmes in the field, on short-term effects for supporting specifically European capabilities in VSAT terminals and system technologies.

For the case of the space segment, the Commission intends to pursue actively, within the framework of EEC competition rules, a debate with EUTELSAT and the member states on how best to achieve the goals of free access to space segment capacity and commercial freedom for space segment providers. In particular, the Commission will seek to ensure that the future scope for alternative offers of space segment capacity competitive to EUTELSAT shall not be impeded.

The Commission will pursue with the satellite and earth segment industry how best to assist in ensuring that they are not placed at a commercial disadvantage vis-a-vis their US and Japanese competition by the advent of a more liberal regime for satellite communications in Europe. In particular, efforts will be made to ensure equivalent opening of corresponding markets in these two countries.

Equally, the Commission will identify the corresponding steps relating to the two global international satellite organizations, INTELSAT and INMARSAT, to ensure that the treatment afforded to the three organizations is coherent.

The final directive is planned to be submitted to the EC Commission as soon as possible. This directive, once adopted, will have a considerable influence on telecommunications, broadcasting, audio-visual and space industries as well as the many new users and service providers, such as education and training institutions. And these new arrangements may impact considerably on Euro-Pacific relationship in terms of new and future economic opportunities in terms of progressive elimination of discriminatory regulations and practices.

What are the latest developments in the field of the high definition television

standards? End of November 1991, the European Parliament voted to approve the plan to introduce HDTV to the EC market but, at the same time, added ammendments which would lower the cost to consumers. The Parliament also agreed in principle to a package of subsidies for broadcasters, manufacturers and cable operators to help make the switch to HDTV. However, the Parliament's amended proposal, which must still be redrafted by the EC executive Commission, may be opposed as too interventionist by some EC governments.

The Parliament voted by a wide majority against a Commission proposal to require all new, large TV sets to have special decoders able to receive high-definition broadcasts after 1993. The decoders would have added substantially to the price of a TV set to consumers. Instead, the Parliament proposed that TV sets be equipped with "standardized sockets" so that the special decoders can be installed as an accessory.

The Parliament adopted HD-MAC, the technology jointly developed by Dutch Philips Electronic NV and Thomson SA of France, as the future standard for HDTV broadcasting. The EC subsidies package would include aid for both companies. However, the Parliament voted to maintain tough conditions for broadcasters by requiring them to begin transmitting in a transitional HDTV standard, D2-MAC, once EC legislation comes into effect. To make the change more palatable, the Parliament agreed in principle to direct subsidies to help satellite operators to simultaneously broadcast conventional and HDTV signals.

The EC Commission will deliver an improved HDTV strategy to EC telecommunications ministers when they meet on 5 December 1991 at Maastricht in order to define their new legislation on satellite transmission standards which expires at the end of the year. A more relaxed directive may satisfy the needs of European broadcasters which have built up an audience for programmes transmitted using different norms, whereas Philips and Thomson have already invested heavily in new technology based on existing EC legislation.

Besides these developments, it should be noted that leading electronic companies originating in different countries in the world are now working together on HDTV. A joint collaboration between French and Japanese teams will implement a system converting the European HD-MAC standard to the Japanese MUSE standard. In addition, Sony and Matsushita (JVC) are holding talks to buy Thomson licences of D2-MAC which would amount to 3.6 or 8 ECUS per TV set, depending on the nationality of the firm and its industrial commitment in the EEC. At the same time, eight Japanese and two American companies have agreed to work together to develop large scale integrated circuits from Japan's HDTV sets. The aim is at sharing the huge cost of developing smaller, cheaper, more sophisticated integrated circuits by 1993 in order to speed the popularization of HDTV. This agreement follows similar collaboration announced previously by Japanese firms.

These few examples show many striking features. Introducing a complex new product like HDTV involves coordinating a whole array of often conflicting interests, those of broadcasters, national governments, film makers, satellite operators and electronic companies. A proliferation of competing formats will lead inevitably to a fragmented market for some time. In the medium term, history may repeat with HDTV like with videocassette players during the 1980s, when electronic concerns launched three competing types and when only one prevailed, and that one was based on a Japanese standard. If lessons are to be drawn from history, setting standards would indeed be of little use as a protectionist tool. Europe's PAL and SECAM standards have not prevented Japanese and Korean manufacturers from obtaining an increasing share of the EC market for TV sets.

In light of the preceding analysis, a major change of the regulatory environment seems necessary. That is why I would like to submit the following policy proposal regarding increased co-operation between Europe and the Pacific Area in the field of satellite policy, in order to exploit fully the existing Euro-Pacific synergies.

Parties concerned, together with relevant national, regional and international organizations, should work towards the establishment and adoption, where appropriate, of international standards.

To this end, better information on the standard process is required, as a reference for decisions to be taken and in view of the utmost importance of such knowledge in the context of the rapid technological developments at national and international levels. Participation of all interested parties would benefit the discussions, at a preliminary stage, leading to the elaboration of a given standard. An additional point would be the consideration of all possible elements in the analysis conditioning the formulation of the best possible standards. In trade policy terms, this would mean inter alia (1) monitoring closely the standard process to evaluate properly the cost-benefit parameters; (2) understanding the implications of an emerging standard, in terms of its usefulness, its potential profitability of alternative emerging standards; (3) ensuring maximum transparency in standard processes, with adequate platforms for discussions and mutually recognized testing facilities; (4)reinforcing efforts towards open functional standards so that compatibility and interoperability, along with increasing networking, facilitate switch-over to new technologies.

The above policy proposal should be replaced in its global strategic context, that is whether public and private interests want to favour investments, jobs creation, growth of world trade or whether preference is given to political and economic confrontations. Europe is the highest economically integrated region of the world. The Pacific Area, embracing the Americas as well as the Far East, is on the cutting edge of dynamic economic growth. Countries in the region

currently produce nearly half the world's output of goods and services and account for more than one-third of global trade.

Countries in the Pacific Area are improving actively telecommunications at home in order to sell services to nearby nations. East Asian countries now want to build and launch new commercial satellites in the region. The Republic of Korea, Thailand and Malaysia have decided to compete with Japan, China, Hong Kong and Indonesia as providers of regional satellite links. This new trend will reduce the region's reliance on INTELSAT for television, radio, telephone, facsimile, telex and data transmission via satellite. Satellite operators will in future compete on the basis of low price and quality of the service, including specialized facilities for education, commerce and industry.

There is a growing demand for a full range of high quality communications services to keep pace with rapid economic growth in the Pacific Area. Korean Telecom, a government agency, is due to announce the prime contractor for its first-ever communications satellite project, with about $400 million, in the next few weeks. Companies bidding for construction of two satellites include Hughes Aircraft Co. and Loral Aerospace, both of the United Sates, and British Aerospace PLC of Britain. The satellites are due to be launched in April 1995 and October 1995.

Malaysia recently signed a memorandum of understanding with Hughes for at least one, and probably two, communications satellites to be launched by Arianespace, the European space-launch consortium.

Once the first Malaysian satellite is operational in 1994, it may save up to $15 million a year on use of foreign satellite facilities.

The Indonesian government, which operates two satellites and lease circuits on them to state and private companies in Malaysia, the Philippines and Thailand, would launch a third satellite in July 1992, on a US Delta rocket at a cost of $72 million. This would bring the launch forward from 1995 to meet rapidly growing domestic and regional demand.

In Thailand, a locally listed telecommunications company, Shinawatra Computer Co., has signed a contract with Hughes to build two satellites for launch in 1993. The Thai government in July 1991 awarded this Company, which is 9.5 per cent owned by Singapore Telecom, exclusive rights to operate Thailand's first commercial satellite network. The company was given a 30-year concession, including an eight-year guaranteed monopoly, for the project. But the government has indicated recently that it might modify the Shinawatra contract to allow greater competition.

Overarching all this are the world-wide GATT multilateral negotiations whose successful conclusion is to be one of the most critical economic policy issues facing the international community. One does not underline enough the significance for each of the economies in the Pacific Area and in Europe, of an open and strengthened multilateral open system. A major and significant outcome to the GATT negotiations on goods and services trade, including telecommunications, is necessary to underpin the growth of world trade, to forestall protectionist pressure, to instill confidence in markets and to facilitate the continuation of economic reforms where this is needed imperatively.

Causality Between the Telecommunications Sector and the National Economy

Hanssak Kim
Korea Telecom Research Center
Seoul, Korea

ABSTRACT

Formal analysis of the causal relationship between the telecommunications sector and the national economy has often been neglected, despite the wide acceptance of the notion. Such an analysis will be helpful in extending our understanding of the relationship. In addition, clarification of the relationship will contribute in establishing rational investment priorities among competing sectors of the economy of which the telecommunications sector is a component. Granger causality test is utilized in this study to formally clarify the issue.

1. Introduction

It is widely accepted that telecommunications and the national economy are closely related to each other. This notion is supported by the claims that the telecommunications sector requires huge investments which in turn demands healthy financial support from the national economy and that the national economy is boosted by the high value added telecommunications industry. These claims not only pose interesting questions to economists but also have important policy implications. The first idea implies that a higher priority should be placed on the telecommunications sector, while the second argument suggests that the priority should be shifted to other sectors of the economy, preferably with high value added and less capital intensive industries. An analysis of these claims will be useful, especially for those countries with limited investment resources, for efficient resource allocation and establishment of rational investment priorities are crucial.

Surprisingly, though, few studies attempt to clarify the causal relationship between the telecommunications sector and the national economy, which is the motivation of this paper. The result from an empirical analysis of the relationship in Korea and some selected countries suggests that the causal relationship is not decisive. However, there seems to be a tendency that the telecommunications sector is preceding and causing the national economy in less developed countries while the situation is reversed in advanced countries. The organization of this paper is as follows. Section two discusses the methodologies of the causality test and the related issues of stationarity and co-integration. Section three discusses empirical results of the causality test in Korea and some selected countries, with implications and conclusions contained in the last section.

2. Methodologies

The test of causality and the macro-economic input-output analysis may be utilized to clarify the issue. These methods have different uses. The causality test reveals which variable causes which variable. That is, it tests whether a change in a variable causes and preceeds a change in another variable. On the other hand, the input-output analysis has a limited use in clarifying the question of which of the two variables causes the other. In the input-output analysis, flows of products among industries are tabulated, and the inter-dependences of the industries are identified. Impacts of an industry on others may be analysed on different points in time (usually every 5 years) to obtain a comparative static view of the industrial structure of an economy.

In the present study, the causal relationship between the telecommunications sector and the national economy is analysed utilizing the causality test suggested by Granger. The number of telephone lines (or the size of the exchange capacity where available) and constant price GNP (current GDP for foreign countries) represent the telecommunications sector and the national economy, respectively.

Common econometric practices when analyzing the relationship between the telecommunications sector and the national economy are to regress the former on the latter. The reason for the practices may be that, in estimating and forecasting telecommunications variables, national economic variables, such as GNP, are employed without a verified causal relationship between them. It also seems that such practices are based on the common and vague belief that the telecommunications sector and the national economy are closely related each other. These types of regression analyses can only be justified by their generally high explanatory power as indicated by R^2.

Another problem may come from the fact that these equations are usually estimated by the OLS (ordinary least squares) method. Recent studies by Granger and others warn that the OLS method does not yield consistent and efficient estimates when the series concerned are non-stationary and not co-integrated each other. It is likely that a time series with a trend (GNP is a typical example) is non-stationary. Consequences may be that if the other variable-- in our present study, the number of main telephone lines--is also non-stationary and if both variables are not co-integrated, the estimates from the OLS regression are spurious. Therefore, it is necessary

that we inspect the two variables for stationarity before any regression is done. If they are found to be stationary, it is fine to use the OLS. If not, it has to be clarified whether they are co-integrated. If they are co-integrated, the OLS will be consistent. Otherwise, the regression will be false and meaningless.

Unit root tests, of which Dickey-Fuller test is the most popular, test the stationarity of the variables. If the coefficient α_1 in the regression,

$$\Delta X_t = \alpha_0 + \alpha_1 X_{t-1} + u_t,$$

is significantly different from zero, the hypothesis that X has a unit root is rejected. That is, X is found to be stationary. However, in testing the significance of α_1, the usual t statistics may not be used. Instead, t statistics in Granger & Newbold must be used, as in table 1 below. As can be noted, the critical values are greater than the usual critical values for the t-test.

When and if the variables are found to be non-stationary, it is necessary to find out whether they are co-integrated by running a regression of the form

$$X_t = \theta\ Y_t + u_t\ .$$

If X and Y are co-integrated, that is, if there exists θ (called the co-integrating scalar or vector) such that a linear combination of X and Y (X - θY) is stationary, the OLS is able to provide a consistent and efficient estimate of θ. Specifically, we may test whether the residual of the above regression is stationary by the unit root test. Alternatively, we may also test whether the autocorrelation coefficient of the above regression is significantly different from and smaller than unity by inspecting whether the DW statistic is significantly different from zero. If the residual is stationary or the DW statistic of the above regression is significantly different from zero, X and Y are co-integrated such that X - θY is stationary and the OLS method is justified. Critical values of the DW statistics for the test are also included in Table 1 below.

Critical Values \ Significance Levels	1%	5%	10%
t statistics	3.77	3.17	2.84
DW statistics	0.511	0.386	0.322

Note: From simulations based on 100 samples with two random walk time series.

TABLE 1. CRITICAL VALUES FOR UNIT ROOT TESTS

After the preliminary test for the unit root, we proceed to the causality test. Of several methods, we will utilize the simplest Granger test. This method checks if lagged terms of the independent variable have additional explanatory power when lagged terms of both the dependent and independent variables are included in the regression. If that is the case, the independent variable is said to cause the dependent variable. This method uses the usual F test.

3. Estimation Results

3.1. Stationarity Tests

Data utilized in this study are Korean quarterly GNP in 1985 prices from 1970:1 to 1989:4 and the number of telephone lines from 1981:1 to 1991:1. Estimated lag structures of the variables, according to the estimated partial autocorrelation coefficients, are such that GNP have five lags while the number of telephone lines has one. The estimated lag coefficients are as follows.

$$GNP_t = \underset{(-.4)}{-72.15} + \underset{(6.6)}{.64}\ GNP_{t-1} + \underset{(.3)}{.007}\ GNP_{t-2} + \underset{(.6)}{.01}\ GNP_{t-3} + \underset{(47.1)}{1.0}\ GNP_{t-4} - \underset{(-6.4)}{.64}\ GNP_{t-5}$$

$R^2 = .994$, DW = 2.26, SSR = 21,812,229,

SSE = 562, degrees of freedom = 69

$$Exlines_t = \underset{(2.0)}{110{,}032} + \underset{(166.2)}{1.03}\ Exlines_{t-1}\ ,$$

$R^2 = .999$, DW = 1.73, SSR = $78*10^{10}$,

SSE = 142,946, degrees of freedom = 38.

Note: Exlines denotes the number of telephone lines, and numbers in parantheses are t statistics.

Getting the estimated relationship, we now proceed to test for unit roots.

$$\Delta GNP_t = \underset{(1.9)}{1{,}881} - \underset{(-1.69)}{0.10}\ GNP_{t-1}$$

$$R^2 = 0.036, \quad DW = 2.84$$

$$\Delta Exlines_t = \underset{(2.0)}{110{,}032} + \underset{(4.3)}{0.026}\ Exlines_{t-1}$$

$$R^2 = 0.33, \quad DW = 1.73$$

We find that GNP has a unit root while the number of telephone lines does not. Since GNP has a unit root, we need to test if both variables are co-integrated.

$$Exlines = \underset{(-2.75)}{-2{,}019{,}682} + \underset{(13.4)}{450.8}\ GNP$$

$$R^2 = 0.84, \quad DW = 2.06,$$
degrees of freedom = 34.

From the DW statistics, we find that they are co-integrated. We accept that both are co-integrated in the sense that a linear combination of them is stationary even when only GNP is non-stationary.

3.2. Causality Test-Korea

Since both GNP and the number of telephone lines in Korea are co-integrated, we now discuss the causal relationship between them. F tests are used with 5 lags of both variables in the regression, for GNP was estimated as a fifth order autoregressive process. The estimation and test results are summarized in Table 2 below. As indicated in the table, the null hypothesis that either GNP or the number of telephone lines does not have any additional explanatory power when the lagged terms of the other variable are included in the regression cannot be rejected at the 10% significance level.

That is, the causal relationship is meager so that the other variable does not have additional explanatory power when the lagged terms of the dependent variable are included. It is noteworthy that although the F statistics are not significant in both cases, it seems that the number of telephone lines causes GNP more than GNP causes the number of telephone lines, as indicated by the relative magnitude of the statistics. Thus, at least during the sample period in Korea, a regression of GNP on the number of telephone lines seems more appropriate.

Dependent Variable			GNP	Telephone Lines
Independent Variables	Intercept		7380.9 (2.5)	-314,300.4 (-0.5)
	GNP	lag1	0.29 (1.4)	20.3 (0.5)
		lag2	-0.22 (-2.4)	10.7 (0.6)
		lag3	-0.22 (-2.5)	10.9 (0.6)
		lag4	0.81 (8.8)	26.3 (1.4)
		lag5	-0.54 (-2.6)	-17.9 (-0.4)
	Telephone Lines	lag1	0.0005 (0.5)	1.2 (5.0)
		lag2	-0.0006 (-0.4)	-0.4 (-1.3)
		lag3	0.0014 (1.0)	0.8 (2.6)
		lag4	-0.0008 (-0.5)	-0.7 (-1.8)
		lag5	0.0012 (0.7)	0.1 (0.3)
Statistics	F Statistics		1.91 [0.14]	0.97 [0.46]
	R^2		0.994	0.999
	DW		2.317	2.042

Note: Significance levels in square brackets and t statistics in parantheses. F statistics are for the hypotheses that the lagged terms of the variable in question do not have any additional explanatory power when the lagged terms of the dependent variable are included in the regression.

TABLE 2. CAUSALITY TEST RESULTS

Few points deserve special attention. Firstly, there may be a problem of instantaneous feedback. If the instantaneous feedback occurs within the frequency of the data, the causal relationship detected above may be invalidated. The use of the quarterly data is to avoid the problem as much as possible, and the probability of the instantaneous feedback between GNP and the number of telephone lines occuring within a quarter seems to be fairly low. Secondly, since both the F statistics are not significant, the causal relationship in one direction is not necessarily stronger than the one in the other direction. All that can be said is that a causal relationship in one direction tends to be stronger, with definite conclusions to be drawn with further evidence. Thirdly, the telecommunications sector is a part of the national economy GNP figures represent. Hence,

in a sense, one may argue that our discussion of the causal relationship between the telecommunications sector and the national economy is similar to arguing whether consumption causes GNP or not when consumption itself is a part of GNP. However, the telecommunications sector is not as large as consumption, albeit growing, in the national economy. Thus, the growth in the telecommunications sector may not cause statistically significant changes in the national economy when other sectors are instantaneously growing as well. In addition, our regression exercise is analogous to running a standard regression of consumption on national income while consumption is a component of the national income at the same time.

If we tentatively accept that GNP is caused by the number of telephone lines, the regression yields,

$$\log (GNP) = \underset{(475.6)}{0.630} \log (Exlines)$$

$$R^2 = 0.831, \quad DW = 2.392,$$
degrees of freedom = 41.

The elasticity of 0.63 implies that 1% growth in the number of telephone lines causes GNP to grow by 0.63%.

The Korean telecommunications industry was lagging behind the growth in the manufacturing industries in the 70s, but catched up rapidly with other sectors in the 80s, backed by strong demands from industries and consumers and by sustained investments made possible by healthy economic growth. It will be very interesting to find out whether the causal relationship in the 70s and the 80s are any different. Unfortunately, however, the Korean experience in the 70s cannot be empirically evaluated at this time, due to the lack of appropriate data.

3.3. Causality Tests-Other Countries

The investigation of the causal relationship between the telecommunications sector and the national economy for other countries is performed using the annual data from ITU. Gross Domestic Product (GDP) and the number of telephone lines (or capacity where applicable) of those countries are used. The regression equations take the same functional form as before, except for one year lag due to the different data frequency. Although the data sets for the countries are rather small covering 70s and 80s, consistent and interesting results are obtained. R^2 is usually greater than 0.9, DW statistics indicate no serial correlation, and the variables are co-integrated for virtually all countries considered. The result of the F tests is summarized in Table 3 below.

The F tests are the same as before. Of 32 countries considered, the majority have insisgnificant F statistics, suggesting the possibility of feedback. In addition, for those countries with significant F values, no obvious causal directions seem to exist. For example, GDP causes the growth in the telecommunications sector in South Africa, Ecuador, and Sri Lanka, while the causal direction is the opposite in Indonesia, Bahrain, and others. However, it is interesting to note that advanced countries and less developed countries have distinct patterns. That is, advanced countries, except for Germany, have a tendency that GDP causes the telephone lines, while two thirds of 27 less developed countries have the opposite causal direction.

Countries	F_{tel}	F_{gdp}
Japan	0.83	0.23
Germany	0.38	0.63
France	0.57	0.16
United Kingdom	0.48	0.16
Italy	0.43	0.07
China	0.31	0.65
Mexico	0.24	0.60
South Africa	0.41	0.004**
Poland	0.06	0.07
Columbia	0.18	0.68
Saudi Arabia	0.013*	0.99
Malaysia	0.56	0.67
Singapore	0.62	0.84
Indonesia	0.008**	0.68

Malawi	0.046*	0.011*
Rwanda	0.99	0.22

Significance levels for the respective F statistics.
* **: Significant at the 5% and 1% level, respectively.

TABLE 3. CAUSALITY TEST RESULTS FOR SELECTED COUNTRIES

The result indicates that the telecommunications sector is following the national economic growth in advanced countries, while the same sector may be considered as a leading indicator of the national economy in less developed countries. The reason may be that, in less developed countries, a higher priority is placed on the telecommunications sector and the sector is receiving a preferential treatment in their economic development plans so that the sector is expanding faster than the national economy. In fact, many developing countries place heavy emphasis on expanding their basic telecommunications networks to facilitate their economic growths. On the other hand, the result may also indicate the fact that the growth in the basic telecommunications sector in advanced countries is slowing down. With the use of the cummulative number of the telephone exchange lines as representing the telecommunications industry in a country, the above result may well be anticipated. More comprehensive indicator of the telecommunications industry may be needed in order to further clarify the causality issue.

4. Implications and Conclusions

The causal relationship between the telecommunications sector and the national economy does not reveal itself decisively in Korea and the majority of the countries we considered, possibly due to smaller samples and instantaneous feedback. Nevertheless, the result provides some useful insights. That is, it seems that the telecommunications sector causes or preceeds the national economic growth in less developed countries including Korea, while the opposite tendency is more visible in advanced countries.

As discussed above, the telecommunications sectors in developed and less developed countries may be in different development phases. The result that the telecommunications sector tends to cause the national economic growth in less developed countries may be a reflection of the preferential treatment the sector received in those countries. Nevertheless, the econometric analysis in the present study reveals that the causal direction seems to be from the telecommunications sector to the national economy in less developed countries. It, therefore, suggests that the higher priority has been and should be placed on the sector in those countries. The input-output analysis may help in determining how much emphasis should be placed on the sector.

Some limitations of the present study deserve a brief discussion. The telecommunications industry has been represented by the number of cumulative telephone lines in the study. With the importance of the enhanced telecommunications industry growing recently, the plain old telephone service may no longer be an accurate criterion of how large or developed the sector is. Therefore, our finding should be interpreted accordingly, with one minor justification that the number of plain old telephones may still be highly correlated with the size of the sector, especially in less developed countries, in which case our analysis retains considerable validity. Secondly, as with any empirical study, the result is conditional on the past history and there is no guarantee that the future will reproduce the past. Thirdly, the instantaneous feedback may adversely affected our causality analysis, particularly for those countries with annual data.

THE CHANGING ECONOMIC ROLE OF TELECOMMUNICATIONS

JOHN URE
Centre of Asian Studies
Hong Kong University

1. Abstract

The spread of networking is pushing the telecommunications industry beyond connectivity towards an interpenetration with the enterprise sector, and therefore beyond its traditional utility role. This paper, with special reference to Hong Kong, sketches out some of the conceptual and policy issues which require more detailed empirical research. It represents the start of a research project, not its conclusion.

2. Introduction

The full effects of the micro-electronics revolution on the telecommunications industry have yet to show themselves despite the enormous changes that have already taken place. This is partly due to the ongoing nature of technical change and industry innovation within the paradigm of digital communications. But it is also due to the transformative implications of the digital era for entire economies. National economies, most notably that of the United States, are forging ahead into what is loosely described as the 'information age', while elements of the world economy, in particular the activities of multinational corporations, finance and global trading companies, are increasingly dependent for production, cost and marketing information and co-ordination upon computer-generated digitally-transmitted data telecommunications.

So, in practice there are radical changes taking place within the telecommunications industry, and equally radical, but still underdeveloped, changes taking place in the input-output relations between traditional telecommunications companies and the wider economy. This paper sets out to raise some of the issues and problems posed by the inter-action of these two aspects of change.

3. Incremental and Radical Change

Changes that take place purely within a given technological paradigm without changing it in any substantial way are usually referred to as incremental changes. Examples abound of alternative methods which form sub-parts of the overall system. For example, the use of reed-relays in analogue switching, or the development of time division as opposed to space division multiplexing. Where incremental changes induce partial shifts out of an existing paradigm, we could perhaps term it 'incrementally transformative'. Certainly the invention by Strowger of his original switch was transformative, as was the subsequent shift from manual to automatic.

Changes which alter the fundamental principles along which communications are designed, and thereby break the paradigm, are commonly described as radical. There is no question, for instance, that the invention of the microprocessor has had radical effects upon all the technologies to which it has been applied, including telecommunications. But more fundamental was the prior invention of binary language, and the subsequent invention of digital transmission. This universal machine 'alphabet' has produced a transformation of technology which first went beyond hardware into software, and, therefore into 'artificial intelligence', and has now progressed into firmware, and probably has many more stages to go.

The key element to arise from among these radical changes is, in my view, that of artificial intelligence. What makes this key is not the intelligence itself, but the possibilities of it being remotely accessed. On its own, this has opened up networking possibilities, through interconnectivity, which are transforming all types of economic and social activity, killing some off, and giving birth to others.

4. Networking

It is through networking that the telecommunications industry enters, let us say penetrates, the inner commercial life of enterprises, and potentially the inner social life of households. Previously the supply of the plain old telephone service was just an external connection with the world. It penetrated less deeply into the office, the factory or the home than other utilities, such as gas, water and electricity. These other utilities are directly used as inputs in production and consumption activities, such as heating, powering, washing, cooking, and so on, to a degree which went beyond the normal usage of telephony. (Of course, large scale industrial consumption of gas, electricity, etc., is usually organized separately from, or additionally to, the public utility grids.)

But networking has changed all that. Telecommunications has leapfrogged other utilities in the degree of its input into these activities. The way for its doing so was prepared by the computer revolution. From design systems such as CAD-CAM to production systems such as MAP, and from office systems such as TOP, to reservation systems such as SABRE, and not forgetting the basic PC software programmes run from the home, digital communications

networks laid down an infrastructure that could be connected.

The public telephony network, even when predominantly analogue, was drawn into these developments fairly early on. PCM (pulse code modulation) techniques enabled the analogue network to transmit digitally-coded voice and data between exchanges or between data terminal equipment. In the case of Hong Kong, for example, the H.K.Telephone Company introduced PCM as early as 1962 in PABX equipment, and introduced PCM into the public switched telephone network as early as 1967, giving cause for the Company's inhouse journal "Hello" to proclaim itself "in the forefront of technical advance" (December 1967).

Public data networks, often as overlays in the first instant, were the next step. The Macau Telephone Company (CTM), a very small administration by world standards, offers a good recent example of this development. A digital data network now overlays the public switched network offering data circuits and packet switching, but because this network is operated independently, and would not, for instance, survive a restart procedure in the event of a crash in the PSTN, it does not, as yet, offer the full range of services, such as virtual networks. It is therefore a good illustration of the time, planning and investment required to transform an old analogue system into the latest technology.

These public data networks exist to win business from private users. To do that they must encourage private user networks to interconnect, but that interconnect is also the first step towards penetration. The data transmitted is typically computer-generated and computer-stored. From the transmitting end the public network just receives for onward carriage, but at the other end there naturally arose the possibility that the data received had been in some way enhanced, perhaps reformatted, or perhaps stored before delivery or routed to find the lowest-cost transmission path, or perhaps delivered to multiple destinations. The generic term 'value-added' is a loose one, but 'value-added' networks were the obvious next phase. Within the term 'value-added' can be identified quite different types of services. Some clearly enhance the data. Others simply save money by store-and-forward techniques and routing routines. Others package and sell 'information' as a commodity, yet others just transport the information packaged and sold by others. But in many cases the information or data in question is fed directly into the machine-technology which lies at the heart of many commercial activities. In other words, the information, which is generated beyond the enterprise, is used directly in the wealth-generating process of the enterprise.

It is at this stage of network development and connectivity that we can properly say that telecommunications goes beyond the traditional functions of a utility. Telecommunications goes beyond being just a form of transportation or means of carriage. Therefore the National Telecommunications and Information Administration (October 1988, p.3) of the US Department of Commerce was not wrong to say that

> "Today is the 'Information Age', and telecommunications comprises its chief transportation system."

but it does not go far enough. It does not fully recognize the telecommunications function as becoming part of the directly productive economy in a way which far exceeds the traditional role of telephony, or that of the other utilities. Indeed, in many cases the micro-electronics revolution has diminished the relative importance of energy inputs, and information technology has substituted for both labour and energy requirements. Flexible manufacturing systems, and Just-in-Time work routines, both of which save on resource use, would not be possible without telecommunications services.

5. Connectivity and Inter-Penetration

One of the important areas of value-added services is connectivity, the ability of a value-added network to connect one company's private network to other networks which do not share the same architectures or use the same protocols. This service offers value-added service operators the opportunity to market themselves as managers of networks on behalf of companies. Small or medium-sized firms with limited resources or know-how often find this to be a cost-effective solution when their business depends to a high degree on communications.

What this development is in effect doing is to bring the network operator right into the heart of the firm's commercial activities by running facilities that would otherwise be internal to the firm. Of course, how far this goes will vary with circumstances, but it is what I would term 'penetration' as opposed to simple connection.

Value-added network operators are usually companies with substantial experience in the computer industry, although telephone companies also offer VANS. In the case of Hong Kong, for example, Hong Kong Telecom offers a wide range of network services, especially to local firms, but they tend to involve less enhancement than, for example, the range of value-added services offered by companies like IBM. This market 'division of labour', which is the subject of a current research project, perhaps reflects the traditional specialization of companies coming from the two different ends of the computer-telecoms sectors.

But there are direct parallels between the two sectors, even as they overlap, if not merge. Centrex is an obvious example, whereby a telephone administration attempts to draw business onto the public network by substituting for the traditional PABX. Again this goes beyond connectivity towards penetration. At the heart of this penetration lies the ability of the private company to access, remotely, the artificial intelligence programed within the public switch, and the ability of the telephone company to provide the service, such as direct

dial-in, call-waiting and forwarding, voice messaging, etc.

6. Telecommunications and Competition

But penetration can go both ways. Remote accessing means that an enormous technical and commercial potential exists for bringing telecoms applications directly into companies, and indeed for the migration of certain functions from the public to the private domain.

Two major factors would seem to be at work here. First, the spread of private networking through the economy. This is likely to be a function of general economic development, and of the advancement of an economy from an agrarian and manufacturing base towards a tertiary economy and a world trading status.

Second, the relative cost advantages involved. These will be determined by, among other factors, the geography of the operating environment and the pace of technological advance. Geography will influence relative costs, for example of switching and transmission, or of cable versus microwave, whereas technological advance will bring different systems within affordability, compatibility, and so on.

In a major study of these developments for the US Department of Justice, Peter Huber (**The Geodesic Network**, 1987, p.1.3) puts it thus

> "Fiber-optical cable has slashed transmission costs for high-density applications, but the last mile of the network, where about half the transmission expense arises, carries mostly low-density traffic. In the past fifteen years, on the other hand, revolutionary developments in electronics have slashed costs of switching and other forms of network intelligence. The inexorable trend is therefore to move switching out toward the end user. Making connections at a distance costs more in increased transmission than it saves in lowering the number of connections needed. As a result, every network node is sprouting new arms."

But in the case of Hong Kong the economics differ. Because business and residential subscribers are packed into a small and densely crowded territory, telephone exchange areas tend to be small and exchange multiples large, averaging around 40,000 lines. To quote the General Manager, Engineering, Mr Peter Skerrett (Teletopics, March 1989)

> "The capital expenditure profile to provide telephone service is markedly different from many other urban cities. Unlike them, our potentially expensive items are land and buildings and the least expensive being external cabling."

Other things being equal, the economic profile of the Hong Kong PSTN would therefore tend to work against the migration of switching from the exchanges out towards private network nodes. A further disincentive to such a development is the absence of a local voice message-rate in Hong Kong, and all domestic calls are local. Thus there is little incentive to by-pass the PSTN for voice calls, or for fax. And since leased circuit prices are kept low within Hong Kong, there would be less incentive to build private networks, involving private cabling or microwave transmission, which by-pass the public network.

But there are other, independent, reasons why enterprises wish to develop networks, and carrying voice and fax alongside data and possibly video to connect suppliers, buyers or agents may well become a future feature of networking within Hong Kong as elsewhere.

7. Hong Kong's Special Economic Character

Undoubtedly one important source of impetus which operates in Hong Kong arises from the growing insistence by international clothing retailers that their many Hong Kong-based suppliers of fabrics, garments and sportswear switch over to some form of EDI (electronic data interchange). There is, in other words, a strong 'pull' factor involved here, emanating from beyond Hong Kong.

Unlike Singapore, where the Government decided that Singapore shall have EDI, the Government in Hong Kong has been painfully slow in formulating an EDI policy and seems to be torn between the market-led solution and the dirigist approach. But if the Government decides in favour of at least a partially State-led initiative, the spread of electronic communications systems among smaller and medium-sized businesses is likely to accelerate significantly.

A second strong source of EDI and private network systems within Hong Kong comes from local large companies, especially in the broad fields of transport (shipping, air-freight and passenger, the Metropolitan Rapid Transit system, the Kowloon-Canton Railway, cabs, trucking) and finance and trading houses. Naturally, it is among these companies that the most sophisticated equipment users and private network operators are to be found.

These larger companies dominate network use and international communications from Hong Kong, and it is their commercial activity, together with the excellence of Hong Kong's public telecommunications facilities, that draws multinational companies to use Hong Kong as a regional communications hub. But it is the dominance and nature of small and medium-sized firms which really differentiates Hong Kong from many of its neighbours, giving Hong Kong its unique economic and social character.

Table 1 provides a broad overview of Hong Kong's domestic industrial-economic structure, 1980-1988, which for a working population which grew

from around 2.3 million to around 2.8 million (from a total population which grew from just under 5 million to just under 6 million) immediately suggests a preponderance of small employers. The figures in small brackets represent the percentage contribution of each sector to the gross domestic product. It will be seen that the private sectors which have grown in economic importance are the wholesale, retail, restaurant and hotel trades, the personal and community services sector, and utilities. The first two of these sectors have a very high percentage of small businesses. The employment/establishment ratio in wholesale, etc., fell from 6.4 to 6, and in services fell from 11.4 to 10.9.

TABLE 1

Establishments and Persons (000s) Employed By Public and Private Sector in Hong Kong

(Percentage Contribution to GDP at Current Prices in Brackets)

	1980 Est.	1980 Staff	1988 Est.	1988 Staff

Source: Sit,F-S and Wong,S-L (1989) **Small and Medium Industries in an Export-Oriented Economy: The Case of Hong Kong** (University of Hong Kong, Table 3.2. See original for reporting problems.)

manufacturing establishments by 1985, employed 71.9% of manufacturing workers, and accounted for 65.4% of manufacturing output (gross value) and 64.1% of manufacturing value-added. (See Table 2) All these proportions were higher than in 1971.

As they point out, the fact that small and medium-sized firms have grown in significance as Hong Kong's economy matured is testimony to their entrepreneurial flair and relatively high productivity rather than to backwardness and low productivity as would be the case in some other economies. But smallness inevitably means certain weaknesses to the Hong Kong manufacturing base, especially in the area of research and development. Economies of scale are not available to support such activities. But economies of scale are attained in another way, by a high degree of specialization by small firms in their range of production which enables them to afford to use automated equipment. (See Sit and Wong, 1989, p.28).

They further stress the important role of import-export houses which provide the marketing services essential to the survival of these small firms. Much of Hong Kong's manufacturing

base depends upon international sub-contracting arrangements which often hub in Hong Kong, but pass on further to Macau, Southern China and other Asian countries.

Now those kinds of arrangements clearly involve considerable communications because the chain is long, and also because the chain branches out. On the other hand, the specialist role of import-export houses probably acts to limit the total communications of any one small firm. So, on the face of it, this structure would not tend to generate a great demand for telecommunications among the producers themselves.

At another level, the essentially small-batch character of specialized production, characteristic, for example, of fashion goods industries, has lent itself elsewhere (notably in Northern Italy) to flexible manufacturing systems which are intensive users of telecommunications. Increasingly Hong Kong's manufacturing base is slipping across the border into Southern China where labour is considerable cheaper and plentiful, and this can be expected to retard greater capital intensity within the industries concerned, and possibly retard also greater communications and information-intensity.

This poses an important strategic issue for Hong Kong. Will the manufacturing base just wither away, and will the tertiary sector be capable of generating sufficient tradeable services to maintain living standards and rising expectations? Or is there scope for a leaner manufacturing base to shift to higher value-added tradeable output? If the latter course is pursued, the role of telecommunications would be a vital element in the restructuring of industry. Seeing telecommunications in this light is to examine it as a possible catalyst of change, whereas traditionally it has been treated only as responding to changes in demand. The provision of electronic infrastructures and the marketing of services tailored to small businesses ahead of demand, and in anticipation of future change and growth, are activities where markets and public policy could meet each other.

The more obvious source of growth in demand for telecommunications services and the use of private networking in Hong Kong lies within the tertiary sectors identified in Table 1 as growing in economic significance. Many of these activities do constitute tradeable services, most clearly those associated with the tourist and business travel trades. The spread, domestically, of reservation systems and network information services, quickly spring to mind.

The highly active property markets in Hong Kong are also another potential source of demand for information services, but the significant moment would arise when these were interconnected with networks devoted to finance and loans data. That would be the point when networking would go beyond an information service 'bought in' and would penetrate the commercial activity of property agents and finance houses.

Many of these developments are already well established, or are rapidly being established, in advanced economies like the United States. But for most countries of the Asia region, including the tiger economies (tigers are more real than dragons, and perhaps less exclusively Chinese!) they are just beginning to unfold. But they are doing so at a time when the computer-based digital technologies of telecommunications are growing beyond their adolescence, which means that appropriate and affordable technologies are now becoming available for smaller enterprises and less wealthy communities.

8. Policy Implications

There are two key areas in which policy will need to develop the role of telecoms in territories like Hong Kong. The first will be the question of network growth itself. It is obviously central to the long term competitive advantage of an economy, both regionally and globally. In the case of Hong Kong it may well be that the services offered across the PSTN, the public data network and the value-added services networks will be vital to the spread of company networking.

The second is the question of competition and choice provided by the telecommunications industry. When telecoms was simply the PSTN and not a lot more, its utility role was foremost. Competition could only be conceived in terms of alternative public networks. In the age of private networks, with growing technical and economic opportunities for the migration of telecoms functions across networks as interconnectivity gives rise to interpenetration, there also arise new opportunities for entry, and new points of entry

But this is likely to be selective entry. Possibly by sector. For example, transportation companies already have well-developed global closed-user group networks which have potential for wider access and usage. Likewise, cable TV systems clearly offer enormous opportunities. Possibly by niche markets. For example, bulletin boards could become entry points for a whole range of consumer services.

For a small territory like Hong Kong, these are vital, possibly strategic, issues. They point to the need for the authorities to view telecoms policy in a broad light, and not in narrow terms of public network competition alone. Privatization and public network competition were very much the themes of the 1980s, but that was a decade of transition. The trends outlined above suggest the terms of public policy need to be very much more comprehensive than previously conceived.

Toward An Intelligent Wireless Network

Donald R. Woodwell
IBM Corporation
Research Triangle Park, USA

1. ABSTRACT

This presentation describes the evolution of wireless networks from today's emphasis on wireline connections to tomorrow's emphasis on services and global accessibility.

2 WIRELESS COMMUNICATIONS ENVIRONMENT

2.1 *WORLDWIDE TREND TOWARD WIRELESS NETWORKS

This trend is occurring because people want mobility,flexibility and useability with their telephone communications. As European borders become more open, citizens will be traveling more frequently from country to country. They want to be able to take their wireless phones with them everyone and make calls within a different country as if they were at home. Further, they want flexibility in how the call is handled and the way it is charged.

Telecommunications companies and agencies want to provide wireless networks because they can more quickly activate a new telephone. Wireless networks in many Physical facilities are not sufficient to meet the demand for new telephones. Wireless systems are less expensive to develop and deploy for the same reason - no wires have to be routed from a switch to the telephone user.

As such, wireless networks are clearly an alternative to wireline networks. In many countries, wireless is complementary to wireline networks. The promise of global accessibility through personal wireless communications is the major force behind wireless in the industrialized nations.

2.2 TECHNOLOGY TRENDS AND DIRECTION

Analog wireless networks are less expensive that digital networks to implement, and are satisfactory in may countries. When the number of analog channels becomes saturated, digital networks can increase the wireless network's capacity. The digital equipment that enables more calling is expensive, but may be the only solution. Digital processing systems allow for user accessibility on computer databases and provide better integration of both voice and data.

World technical and operational standards are changing to keep place with technology improvements. The leading European work is GSM (Groupe Special Mobile, an active constituent of European Telecommunications Standards Institute [ETSI]). The GSM pan-European Digital Cellular Radio Standard has been developed with the agreement of telecom administrations and industry from western Europe. The standard is intended to remain for 20 years as it relies on state-of-the art digital technology. GSM operates in the 900 MHz frequency band, and will coexist with other cellular services such as TACS (United Kingdom, Spain & Italy) and NMT 900 (Nordic countries and Germany).

GSM provides a standard approach to cellular switching, computer databases (for roaming and user verification), network management, signalling, radio equipment, channel and speech coding, security and data services interfaces.

Roaming is the ability of people to travel from their home locations across intervening countries to a final destination widely separated geographically from home and still be able to use their wireless phone. The ability to roam freely will facilitate cross-border travel and country transition in an open European community.

Technical standards for both analog and digital networks focus mostly on frequency allocation and encoding techniques.

Equipment required for wireless networks are switches for Mobile Service Switching Centers (MSC), microwave or landlines to connect the cells, the requisite radio transmitters/ receivers and transmission antennas, voice data encoding units, cordless user telephones, and computers to mechanize operational management functions.

Operations management systems for wireless networks provide for information processing similar to that used to manage wireline networks. For example, new users must be enabled at the MSC, and their data record added to record filing systems in order to track and charge them for on-the-air calls. The performance of the network must be

monitored and evaluated. Problems detected must subsequently be remedied. IBM has a major interest in providing computers for operational management systems.

2.3 PLANNING FOR WIRELESS NETWORKS

In industrialized as well as newly developed countries, considerable planning for and deployment of wireless networks is taking place. Where backlogs for basic wireline phone service exists, wireless networks significantly reduce the time required to meet demands for telephone.

Telecommunications companies and agencies in countries with well-established wireline networks and low demand for new phones provide wireless networks for the mobiles segment of their population. Wireless network operators in North America, Europe and Japan, for example, have requests for new services. These include free phone calling, voice store and forward, and universal telephone number. These services require computer databases that are located within the wireless network or are accessible in a wireline network. Networks with computer databases are called "intelligent." IBM has investigated intelligent networks, and believes its knowledge of computer data management techniques and its computer and database products can make intelligent wireless networks.

3. WIRELESS NETWORKS

3.1 TYPICAL CELL IN A WIRELESS NETWORK

A typical cell or geographic area in a wireless network serves the needs of both mobile and fixed location users. The Base Transceiver Station (BTS) is the heart of each cell. It operates on a dedicated set of radio channels which are different from the channels used in adjacent cells.

3.2 CELLULAR WIRELESS NETWORK

A group of base stations is controlled by a Base Station Controller (BSC) for functions such as handover and power control. Transmissions among cells and BSC's is with microwave and landlines. A group of Base

Station Controllers is served by a Mobile Services Switching Center (MSC) which routes calls to and from the public switched or data wireline networks.

The MSC sets up the call and then routes, controls, and terminates the call. It also manages the inter-MSC handover and supplementary services, and for collecting charging and accounting information. (Figure 1.)

(BTS, BSC & MSC are GSM terms)

4. COMPARISON OF WIRELESS & WIRELINE NETWORKS

Three wireline networks are local, long distance and common channel interoffice signalling system (CCIS). Comparing these to wireless is instructive for three reasons:

1. to highlight the physical differences and functional similarities
2. to show how they interconnect : and,
3. to illustrate how wireless networks can use CCIS for call set up to wireline networks

4.1 TYPICAL WIRELINE NETWORK

The service area for local telephone company is a city, province, state, or multiple local areas which may be geographically dispersed. Between the separate service areas, a long distance network is needed to provide call paths. Local telephone switches have large numbers of local lines for business, government, and residential access.

4.2 INTERCONNECTION BETWEEN A WIRELESS NETWORK AND LOCAL WIRELINE NETWORK

This inter-connection is necessary in order to connect mobile or personal users to parties in locations such as an office building, school or hone where wireless phones are not available. Cables between the MSC and local switch make the inter-connection possible. (Figure 2)

4.3 TYPICAL LONG DISTANCE WIRELINE NETWORKS

Long distance wireline networks differ from local wireline networks largely in the

geographic area served. The switching equipment has fewer lines and more trunking capacity, and the transmission equipment relies on microwave links and satellites along with both copper and optical fiber.

4.4 INTER-CONNECTION BETWEEN WIRELESS & LONG DISTANCE WIRELINE NETWORK

This inter-connection is necessary to connect wireless users with parties in distant locations. This may be a city 500 km or 5,000 km away of in another country. Such links may be between a wireless caller and another wireless receiver or between a wireless caller and a wireline party.

4.5 COMMON CHANNEL SIGNALLING SYSTEMS (CCIS)

These wireline networks were developed over 20 years ago in the United States for the purpose of setting up calls external to the interoffice trunks. As such, CCIS is an "out-of-band" signalling system that bypasses the trunking network so as to determine if a call can be set up without using trunk channels. This makes for a more efficient

Cellular Wireless Network

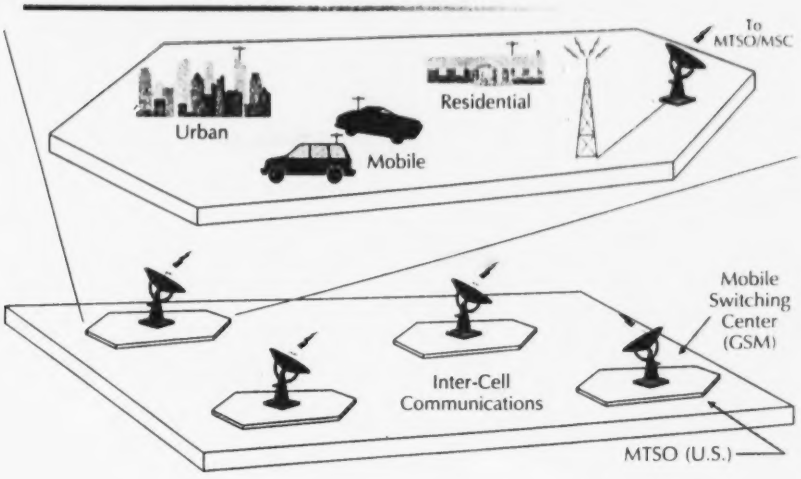

FIGURE 1

Inter-Connection Between Wireless And Wireline Networks

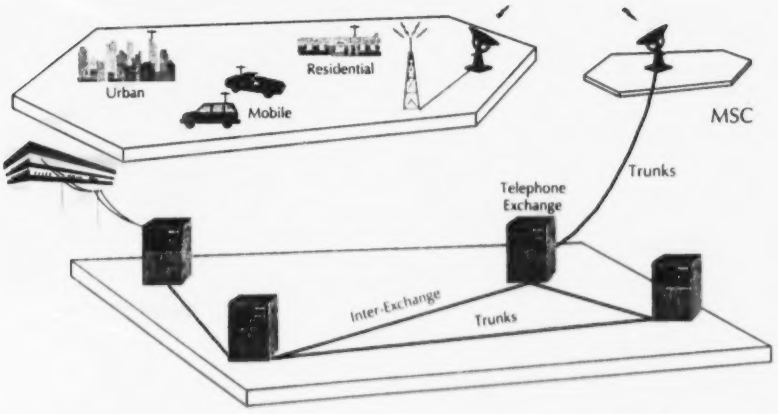

FIGURE 2

use of expensive trunks and allows for more call revenue to be derived from the available trunks.

Early CCIS used a protocol developed by AT&T called CCS #6. In recent years, common channel signalling has worldwide use and the international standards setting organization CCITT developed the CCS #7 standard protocol. This is based on the ISO telecommunications model.

4.6 USE OF CCIS FOR WIRELINE NETWORKS

CCIS call setup is performed by the flow of specialized messages from the originating switching center to the terminating switching center. The originator interrogates their terminator to determine if the line being called is available. If so, the phone of the party being called is rung by the switching exchange office. Simultaneously, a message is sent to the caller's phone. When the party being called lifts the phone off its hook, the call path is completed. After, both parties hangup their phones, the circuit is removed from service by the CCIS messages.

4.7 USE OF CCIS FOR WIRELESS NETWORKS

Call setup is done by the MSC in the GSM standard system. Thus, wireless users who call distant cells on wireline trunks have their calls set up with the facilities of the CCIS and CCS #7. Within the CCS #7 standard there is the Mobile Application Part (MAP) designed for use in the MAP and are carried to the database computer. The database computer responds to the user request and sends its reply via the MAP within the CCS #7 protocol. More will be said about MAP and database access later. (Figure 3)

5 WIRELESS OPERATIONS MANAGEMENT SYSTEMS

5.1 SYSTEM FUNCTIONS

Providing the physical connections and equipment for both wireline and wireless networks is only part of the job of deploying communications networks. Numerous other jobs remain to be done in order to manage these networks. Records must be created for users, physical facilities, line assignments, inventory, network performance, and so forth. This information must be processed and presented to those persons responsible for daily operations, administration and maintenance. Modern telecommunications operators rely upon computing systems to provide the electronic media necessary for storing large amounts of information needed for managing the network.

5.2 TYPES OF COMPUTERS

This chart shows three kinds of computers: a large mainframe for database storage and bill processing; a distributed processing computer; and, a desktop workstation.

The large computer system is required because of the large numbers of files that must be maintained, and the extensive processing required for the applications of call rating (how each call is charged to the user); user billing, invoicing, and printing; and, roamer processing.

The distributed processor is used to control and manage the service order system either within a central customer center of remote

point-of-sale location. The important applications for the distributed processor are service order entry and records maintenance, financial data processing and switch management. (Figure 4)

5.3 MSC FUNCTIONS

The latter is important to the quick activation of telephone service. The MSC switch is connected directly to the distributed processor. When service is requested, a file is created for the new user and an identification number is sent to the switch to enable immediate use of the network to place calls.

The MSC also sends call data records to the billing processor. This automatic input of call records eliminates the need for magnetic tape storage at the MSC switch, and more quickly and accurately updates user billing records. Such accuracy is important to roamer processing to ensure that the most current data is available on the use of the system/

IBM will provide operations management systems in partnership with software vendors.

6. DEMAND FOR WIRELESS SERVICES

6.2 LIFELONG, UNIVERSAL TELEPHONE NUMBERS

People who travel or move locations frequently have a desire for keeping the same phone numbers no matter where they are.

6.3 DIRECTORY ASSISTANCE AND CALL FORWARDING

Users of wireless networks may need to get telephone numbers from the telecom in order to complete a call. As such, they should have a number to call to get operator assistance. Once they have the number, the operator should then be able to connect the user to the party being called (Call Forwarding).

6.4 CREDIT CARD USE AND VALIDATION

Telephone credit cards are a major benefit to business persons and travelers who make frequent phone calls from outside their

Use Of CCIS

Wireless

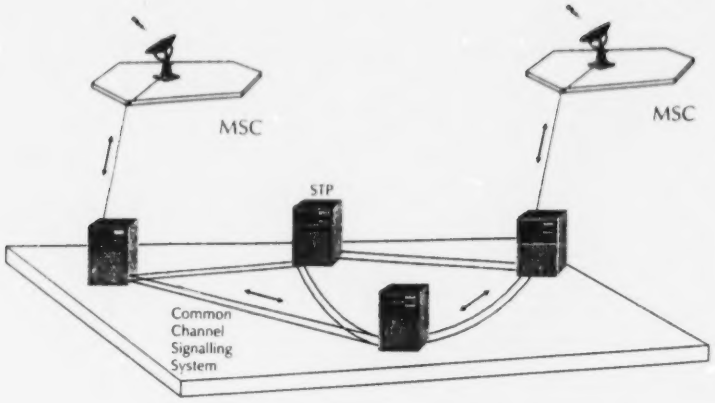

FIGURE 3

Wireless Operations Management Systems

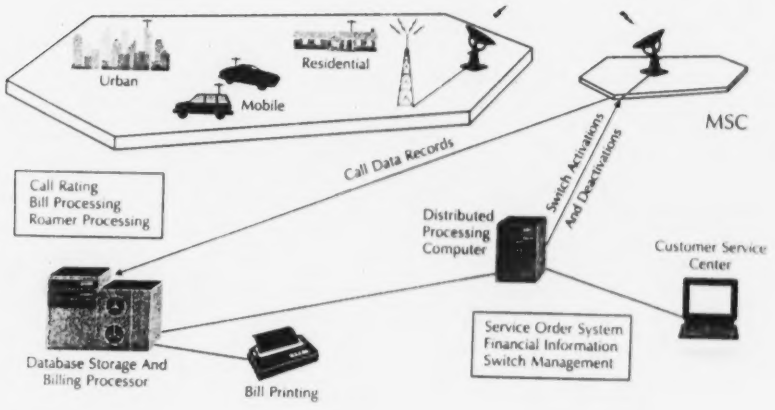

Figure 4

offices and homes. The credit card number is keyed into the numeric pad on the phone and is validated prior to connecting the call. Wireless users will use credit cards as much or perhaps more than a typical wireline user.

6.5 SELECTED FREE CALLS

In most industrial countries, businesses may subscribe to the telecom for a phone number that a customer or client can call with no charge. The business pays for the call. The objective is to increase the number of business calls to provide for more sales and increase customer satisfaction.

6.6 EMERGENCY CALL FROM ANY LOCATION

Telecom agencies and companies are learning that providing emergency telephone service is not only socially important but also an important source of revenue. Wireless users may have more occasion to use an emergency service because of their increased mobility.

6.7 ROAMING (HOME & VISITOR LOCATION REGISTERS)

This requirement for wireless users has been discussed previously. This capability is one of the most obvious benefits of wireless communications technology.

6.8 VOICE MAIL

The capability of leaving a message for someone else in your own voice is a service that has wide spread acceptance. It is an especially useful service whenever a person is traveling extensively.

All the services briefly described here require computer databases that are accessible through the wireless network.

7 INTELLIGENT WIRELESS NETWORK

7.1 CELL DATABASE

Wireless users who need access to a database service may have their request serviced through a local MSC database or... (Figure 5)

7.2 WIDE AREA DATABASE

Their request could be for database services accessible through the common channel signalling system. Today, wireline systems use such a database access scheme for wide-area services. The CCIS is an excellent location for such databases as they cover a wide geographic area. (Figure 6)

7.3 ROAMING

This service is an example of how a database service operates. In Europe, the GSM has decided that it is mandatory that all operators offer roaming service to visitors from other countries. (Figure 7)

The first task for a visitor is the selection of the system to which he wants to connect when outside his home location. Assuming that the home location system is not available at an adequate signal strength, then the user must select from a display of available systems.

Once this is done, then a Visitor Location Register record can be created for this user. When this record is created the VLR signals the HLR with location information in order to retrieve the necessary data for that subject. The subscriber also must be authenticated by the HLR to avoid fraudulent calls.

The roaming system also should be able to properly route calls with the visited area and to charge accordingly. A number of complexities can arise based on where the call originates and terminates within a visited area. Agreements among the mobile networks operators within adjacent and neighboring countries is essential to ensure that roaming users are charged correctly.

IBM will provide computer platforms for wireless services such as Roaming.

8.0 SERVICE CREATION & MANAGEMENT (Figure 8)

8.1 CREATION

New services for wireless users should be quickly and easily created. This implies that services are defined within computer software that is standard and can be used by network operators to fulfill the service requests of their users. State-of-the-art programming techniques are available to enable programmers to write high-quality services software. Workstation computers have the requisite computing capacity for service creation.

Services software operates on standard, commercial-grade computer systems which we call a "database service node." Activation of a service is a simple matter of loading the service software into the computer and transmitting the service user's identification number to the MSC. Workstations are satisfactory for service execution.

8.2 MANAGEMENT

Service Management is an important function as it coordinates changes to the database service node computer files, service performance measurements, interfaces to other operational support systems, helps to ensure the integrity of the database service nodes, and restarts services after a recovered failure. The size of the services network determines the size and type of service management computer.

9 SUMMARY AND CONCLUSIONS

9.1 SUMMARY

The worldwide trends toward wireless are driven by an increasingly mobile society and the need to quickly activate telephones in countries that have very large backlogs of phone requests. Technology is split between analog and digital networks depending on the needs of the country and telecom agencies. Analog is less expensive but digital offers a greater range of services. Planning for wireless is expanding. Countries in the Americas, Europe and Asia are increasing their phone densities for social and commercial reasons. Wireless communications is a way to achieve this objective faster than with wireline networks.

9.2 CONCLUSIONS

Wireless communications have gained universal acceptability as an alternative telephone network. Although wireless connectivity is most important today, new standards and technology improvements will support the growth to new wireless services tomorrow.

New Customer Services Within the Intelligent Network

Harry J. Pettit and Barry J. Sasscer
Bell Atlantic International, Inc.
Arlington, Virginia, USA

ABSTRACT

The introduction of new, market-driven customer services within the Intelligent Network architecture is the subject matter of this presentation. Network operators worldwide see the Intelligent Network as the means to meet their customers' needs and to generate new revenues. The network operators have assessed their customers' requirements and are implementing the Intelligent Network to provide new customer services. In this presentation, I will describe some examples of the Intelligent Network services that are being introduced in Bell Atlantic as well as in the Asia/Pacific region.

1. INTRODUCTION

I would like to set the stage for a discussion of the new Intelligent Network services by first describing the motivation for telephone companies to implement the Intelligent Network. Then, I will review the fundamentals of the Intelligent Network so that we can begin a discussion from a common point. Next, I will summarize the five Intelligent Network services that Bell Atlantic plans to introduce into our network. Finally, I will describe the Intelligent Network services that Telecom New Zealand plans to have operational in 1992.

2. INTERNATIONAL TELECOMMUNICATIONS ENVIRONMENT

I would like to begin by discussing the motivation for implementing the intelligent Network.

I think clearly the one constant feature of the telecommunications environment is that it continues to change.

There are a number of factors influencing the PTTs:

Technology is advancing rapidly in the areas of digital switching, packet switching, fiber optic transport, access through the Integrated Services Digital Network, or ISDN, multiplexing, etc. Telephone companies have come to expect that, increasingly, there will be technological breakthroughs that will permit the transmission of more information across the network to their customers.

Furthermore, the forces of deregulation and privatization are touching nearly every telephone company in the world.

In addition, competition is growing at an unparalleled level. In some countries, licenses have been granted to companies to provide telecommunications services through separate networks that have enabled them to bypass existing telephone networks. Also, in many cases, the exchange equipment providers prove to be the telephone company's biggest competitors by providing switch capabilities in private branch exchanges.

Finally, the customer's requirements have become increasingly sophisticated. For example, through surveys, Bell Atlantic's customers have told us that they want advanced features such as:

- simultaneous voice and data
- higher quality services
- lower cost and improved utilization of services
- greater data speeds
- more network flexibility and customer control, and, most importantly,
- the ability to solve their business problems today.

To be successful, the telephone company must be responsive to these influences by deploying state-of-the-art technologies and by enhancing the network with new features, functions, and services.

The problem that the telephone company faces is the delay in implementing these new capabilities in the network. The amount of time required for local exchange vendors to develop and introduce new features and services into the exchanges can be up to five years from service conception to the actual deployment. This problem has been termed "the software bottleneck." I think it is fair to say that, in today's competitive environment, this is an unacceptable arrangement.

The telephone company requires a network architecture that is independent of the exchange vendor's development schedule.

3. INTELLIGENT NETWORK

Bell Atlantic International has had discussions with telephone companies throughout the world, and clearly they view the implementation of Intelligent Network as a major direction in the 1990s and beyond. They see the Intelligent Network as providing the infrastructure that will allow them to respond effectively to the existing and future needs of their customers.

Fundamentally, the Intelligent Network is a service control architecture that introduces data processing capabilities into the telephone network.

Within the Intelligent Network, there is a centralized data element called a Service Control Point or SCP. The SCP is the heart of the Intelligent Network. It is the repository of information about customers and the capabilities of the network. What is more important is the fact that the SCP contains call processing information in the form of service logic programs. In response to queries from specialized exchanges, service logic programs in the SCP provide directions on how to handle Intelligent Network calls.

Because the SCP is a centralized, general purpose computer, the telephone company can overcome the aforementioned software bottleneck. The telephone company can implement a new service in response to his customers' requirements by coding service application software that will reside in the SCP, rather than in each local exchange.

Essentially, when the local exchange needs to know how to process a call that uses the new service, the following sequence of events takes place:

- the local exchange formulates an inquiry message and sends it to the SCP (if the local exchange does not yet have the capability to create an inquiry message, it forwards the call to an exchange office that does),
- in turn, the SCP queries its databases and sends back instructions on how the call should be handled to the exchange, and
- in response to the instructions it receives from the SCP, the exchange processes the call.

This process occurs in milliseconds.

Now, I will describe the components of the Intelligent Network.

3.1 SERVICE SWITCHING POINT (SSP)

The Service Switching Point, or SSP, is the customer's gateway to the Intelligent Network. The SSP is an exchange with special capabilities. It performs the following functions:

- It recognizes calls that require special handling, that is, the SSP identifies pre-defined "triggers" that mark Intelligent Network calls, such as the "800" dialed digits in the United States.
- It formulates and transmits requests for instructions to the Service Control Point through the Common Channel Signaling Network
- Upon receipt of call processing instructions from the Service Control Point, it completes the call.

Through the efforts of Bellcore and the multi-vendor interaction, or MVI, process, modular and reusable capabilities are being defined for the SSP. These capabilities are the building blocks through which new services will be created.

3.2 SIGNALING TRANSFER POINT (STP)

The Signaling Transfer Point, or STP, is a packet switch that routes messages between network elements within the Common Channel Signaling Network. In the United States, the STP is part of the Common Channel Signaling Network using the Signaling System No. 7 protocol.

Using our example of a typical Intelligent Network call, the STP opens the packet containing the query for call processing instructions from the Service Switching Point. Then, the STP analyzes the query and forwards it to the appropriate Service Control Point and service application. This process is called Global Title Translation. Conversely, when the Service Control Point sends a response back to the Service Switching Point, the STP routes the packet back to the appropriate exchange office.

The STPs are installed in "mated pairs" to ensure continuous availability.

3.3 SERVICE CONTROL POINT (SCP)

As I mentioned earlier, the Service Control Point, or SCP, is the heart of the Intelligent Network. The SCP contains customer and network data as well as service applications. In response to the Service Switching Point's requests for information, the SCP sends call handling instructions to the Service Switching Point.

Today, Bell Atlantic has a mated pair of SCPs that were developed by Bellcore. The two SCPs are located in the Philadelphia, Pennsylvania area and serve the Bell Atlantic Region.

We are presently offering two service applications: 800 service and Alternate Billing Service, or Calling Card service. Bellcore developed these service applications.

Although these service applications are very profitable, they represent only the tip of the iceberg for the possible services that can be provided within the Intelligent Network. The next generation of Service Control Points will offer the telephone company the powerful tool of service creation.

Service creation is the ability of the telephone company to define and implement new services through the coding of service applications software. Service creation enables the introduction of services in a timely and economical manner, independent of the exchange vendors.

The promise of service creation will be fulfilled when two requisites have been met:

- the installation of Service Switching Points with modular, reusable call processing capabilities and
- the implementation of Service Control Points with service applications to direct the manner in which these capabilities are processed by the Service Switching Point.

Bell Atlantic is planning the development of a new Service Control Point. This Service Creation Point will provide a software platform and a service creation environment. Ultimately, this arrangement will move the development of new services from the exchange office vendor to the telephone company and to the customer.

Shortly, I will describe the five new service applications that Bell Atlantic plans to implement in its Intelligent Network.

3.4 SERVICE MANAGEMENT SYSTEM (SMS)

The Service Management System, or SMS, is the operations system for the Service Control Point and the 800 service application. The SMS contains a backup database for the Service Control Point, and it is through the SMS that changes are made to the Service Control Point.

Currently, Bell Atlantic and the other six Regional Companies share a national SMS for 800 service that is located in Kansas. Bell Atlantic has its own SMS for the Alternate Billing Service called DBAS, the Database Administration System.

3.5 SIGNALING ENGINEERING AND ADMINISTRATION SYSTEM (SEAS)

The Signaling Engineering and Administration System, or SEAS, is the operations system for the Common Channel Signaling Network. It provides a network view of the Common Channel Signaling Network and updates the routing tables in the signaling elements.

4. COMMON CHANNEL SIGNALING NETWORK

The Common Channel Signaling Network forms the foundation of the Intelligent Network. It is a packet-switched network that transfers messages between Intelligent Network elements, e.g., between Service Switching Points and Service Control Points, between Signaling Points, etc.

The Common Channel Signaling Network has enabled Bell Atlantic:

- to offer non-database services,
- to support the signaling for the Integrated Services Digital Network, or ISDN, and
- to introduce the database services of the Intelligent Network.

4.1 IQ SERVICES[SM]

The Common Channel Signaling Network architecture is the basis for a number of new services, which allow customers greater control over the calls they make and receive. These services have been tremendously successful in Bell Atlantic.

These new offerings are among Bell Atlantic's family of IQ Services. They use the attribute of the Common Channel Signaling Network through which the telephone number of the calling party, called the ANI (Automatic Number Identification) in the United States, is transmitted to the called party.

The new services are:

- Caller ID
  - Provides the called party a display of the calling telephone number on customer-provided equipment.

SM IQ Services is a service mark of Bell Atlantic.

- Call Block
  - Allows the customer to prevent completion of calls from specific telephone numbers.
- Return Call
  - Enables the customer to return the most recent incoming call automatically.
- Repeat Call
  - Redials busy numbers automatically.
  - When the called line becomes free, the telephone will ring, indicating that the redialed telephone number is ringing.
- Call Trace
  - Records the last call received and sends it to the telephone company.
- Priority Call
  - Provides a special ring for up to six important calling telephone numbers specified by the customer.
- Select Forward
  - Forwards up to six calling telephone numbers specified by the customer.

The penetration of these features has increased steadily in Bell Atlantic. The number of features deployed has grown from approximately 165,000 at the end of 1989 to a projected 784,000 at the end of 1991.

Overall, these services give customers the personal touch that they had in the past when all calls were handled by operators.

4.2 ISDN ARCHITECTURE

ISDN will provide the end-to-end digital connectivity that our customers require.

The Common Channel Signaling Network routes the D-channel signaling for ISDN.

4.3 JOINT STUDY ON THE INTELLIGENT NETWORK

As I mentioned earlier, the Intelligent Network will permit the rapid introduction of new services. To explore these possible services, a Joint Study on the Intelligent Network was conducted by Bell Atlantic, IBM, and Siemens beginning in 1988. The study dealt with the implications of introducing new services into the telephone network through the Intelligent Network architecture.

The three companies formed a number of study groups to explore the various dimensions of the Intelligent Network.

The results of the Joint Study were published in 1989 in the book, The Intelligent Network, which is now in its second printing.

5. NEW INTELLIGENT NETWORK SERVICES IN BELL ATLANTIC

Now, I would like to discuss some of the Intelligent Network services that Bell Atlantic is planning to introduce. Based on our successful offering of the IQ Services throughout Bell Atlantic, we are confident that the convenience and control provided by these new Intelligent Network services will be equally popular.

5.1 ABBREVIATED DIALING FOR MULTI-LOCATION BUSINESSES

This service provides Area Wide Centrex types of features for customers with multiple locations. Stated another way, this service gives the business customer private network types of features over the public switched telephone network. These features include:

- Individual numbering plans
- Directory number portability
- Extension dialing on a multiple exchange basis

The target market for this service is the business customer with multiple locations that are served by different exchanges

For example, suppose a company has two locations. If an employee at location 1 wants to contact his co-worker at location 2, he dials an abbreviated number.

A major advantage of this service is that each employee of the company can maintain the same telephone number even if the employee moves from a location served by another local exchange. Such a move requires an update to the Service Control Point to change the physical telephone number associated with the abbreviated telephone number.

5.2 AREA NUMBER CALLING

This service provides business customers with the ability to use a single telephone number for all

locations or branch offices. Area Number Calling would be particularly valuable to industries such as banking, insurance, retailing, real estate, and fast food, since these types of businesses use numerous branch offices or business locations.

The telephone company will have considerable flexibility in customizing the service for the individual customer. For example, the Area Number Calling service could automatically rout the customer to the closest business location based on the caller's telephone number, or ANI. Beyond geographic routing, the telephone company can provide call distribution by: information requested from calling party, time of day, day of week, date, call distribution among subscriber's location based on percentages, etc.

5.3 OUTGOING CALL SCREENING

This service provides customers with the ability to restrict outgoing calls to specific telephone numbers. For example, in the United States, customers dial numbers with a special prefix to reach sports information, jokes, adult messages, or prayers. They pay either by the call or by the length of the call. In some cases, children have dialed these numbers and have incurred large bills for their parents. Outgoing Call Screening service enables the customer to prevent unauthorized calls to the telephone numbers the customer specifies.

The target market for this service consists of business and residential customers who want to set call privileges to restrict access to certain numbers.

5.4 LOCAL OPINION POLLING

Local Opinion Polling provides for short duration, high-volume calling to media polling events as well as real-time polls conducted through television and radio broadcasts.

Through this service, the SCP collects polling information and forwards the results to a downstream system for tallying.

The target market for this service consists of information providers or data collectors that require calls or calling information to be routed to them.

The calls to the polling number can be interactive or non-interactive.

5.5 INCOMING CALL SCREENING

This service provides a set of features that can be used to establish and manage data connections between users and host computer systems, for example.

The service provides access verification for identifying and preventing unauthorized data users who attempt to access a host system. The network performs the screening of incoming calls. The subscriber determines the conditions for accessing data in the computer, including calling number, authorization code or PIN, time of day, day of week, etc.

The primary market for this service consists of database service providers.

A valuable feature of the Incoming Call Screening is that the Service Control Point could keep track of the telephone numbers of "hackers" that attempt to gain access to the host computer.

5.6 DATA AND REPORTS

This feature enables subscribers to receive raw data or formatted reports about the usage of the five network services previously described. Some examples of the information that could be collected include:

- Times of day that calls are made to a pizza location
- Amount of connect time to a host computer
- Directory number called for customers with Outgoing Call Screening
- PIN used in the attempt to access a host computer

The Service Control Point contains sampling and other special study functions that collect information on calls. Two methods of information collection could be:

- sampling a percentage of calls that use a service
- sampling all calls using a service with certain characteristics, for example, calls from a particular telephone number.

Data can be collected in real time and downloaded periodically to an external processor that assembles the data into reports for the customer.

The target markets for this feature would be: service providers, information providers, and corporate customers that need network management information.

6. TELECOM NEW ZEALAND INTELLIGENT NETWORK SERVICES

Telecom New Zealand plans for its Intelligent Network to be operational in 1992. The Intelligent Network will allow existing services such as 0800 and 0900 to be operated more efficiently but also will provide a number of new services.

6.1 ENHANCED 0800 AND 0900

Enhanced 0800 service will offer customers far greater flexibility and control over how their communications resources are operated and managed. Some additional features that will be available include: call diversion to selected answering points based on time of day, etc.; flexible billing based on volume or distance factors; call barring based on predefined thresholds. Similarly, the existing 0900 service will be enhanced through the Intelligent Network.

6.2 CALLING CARD SERVICES

Calling Card services allow toll calls to be billed to a specific number independent of the originating telephone number. The subscriber must enter the correct personal identification number on the telephone keypad, which is verified in the Intelligent Network database, before the call is completed.

6.3 TELEVOTING SERVICE

Televoting service totals the volume of calls made to certain numbers in response to a request for users to express their views, for example, on a particular issue. The service is often used by television public affairs programs in order to gauge public opinion on matters of current interest.

6.4 AREA WIDE CENTREX AND VIRTUAL PRIVATE NETWORKING

The Intelligent Network provides a platform to expand Centrex service from a local area to a national service so that a large company, for example, can present a single number for callers as well as provide an integrated, closely controlled network for internal communications. The resulting network is termed "virtual" because it appears to the users as if it were a completely separate entity from the public switched telephone network. As a result, the subscriber receives all the benefits of a private network without the expense.

7. CONCLUSIONS

To summarize, in an ever-changing, highly-competitive environment, telephone companies worldwide face the challenge of building a network infrastructure that will enable them to provide services to meet their customers' requirements.

Bell Atlantic believes that the Intelligent Network, with its service creation possibilities, is an integral part of the network of the future. We look forward with great enthusiasm to the implementation of the new Intelligent Network services in Bell Atlantic.

The Intelligent Network Joint Study that I described earlier provided a unique forum where Bell Atlantic, IBM, and Siemens could exchange ideas and learn together.

Bell Atlantic hopes to continue this dialogue with other telecommunications providers. By working together, we will realize the potential of the Information Age.

Development of Intelligent Network and Deployment of Advanced Services

HIROSHI SHIMIZU, General Manager
MASAHIDE OKA, Senior Manager
RYOJI TAKAICHI, Manager
NTT Network Systems Development Center, Tokyo, Japan

1. ABSTRACT

Telecommunications customers are continually seeking higher quality and more diversified services, as well as the ability to use these services at lower cost. To remain competitive and still satisfy customer requirements, NTT must provide more advanced services rapidly and efficiently. For these reasons, NTT has created a new network, a solid step forward towards what is now referred to as the "Intelligent Network Era." This report describes the NTT's Intelligent Network architecture, evolution, component technology, and implemented services.

2. INTELLIGENT NETWORK

2.1 OBJECTIVE

The major objectives to make the telecommunications network advanced and intelligent are the following two points.

(1)To satisfy the customer requirements
- -Low cost, high quality service
- -Diversified services
- -Customized service for each customer
- -Customer control of network management functions

(2)To satisfy the network operator requirement
- -Realizing diversified services
- -Rapid deployment of new services
- -Easy introduction of advanced technologies
- -Minimization of facility cost
- -Minimization of operation cost
- -High stability and reliability

Intelligent Network (IN) is a new network architecture which realizes the above customer and network operator requirements. Namely, Intelligent Network enables the network operator to provide a variety of network-wide services at lower cost to meet each customer expectation. Additionally, the wide area service operations will also become available to the network operator to improve the service quality.

2.2 BASIC NETWORK CONCEPT

In order to meet those requirements flexibly and effectively, it is very important to define a fundamental network architecture. Today, there is world-wide active discussion regarding Intelligent Network which can offer various services flexibly.

As shown in Figure 1, the basic network architecture is comprised of the following two broad layers.

(1)Transport Layer
- -Switching
- -Transmission
- -Real-time processing

(2)Intelligent Layer
- -Service and facilities control
- -Network management functions
- -Expandability due to function segmentation

3. TRANSITIONS OF SERVICE IMPLEMENTATION METHODS

The implemented services and the transitions of implementation methods are shown in Figure 2.

3.1 IMPLEMENTATION BY LOCAL SWITCH

The necessary functions to provide new services are implemented by hardware or software modification in local switches. For example, the services implemented by this means include Call Waiting, Three Way Call, and Call Forwarding, etc.

As the type of local switch software increases, the development of new services will become more expensive and require longer time. Also, as the number of local switches increases, the software or hardware modification will require more manpower to provide nation-wide services.

3.2 PRE-INTELLIGENT NETWORK

The necessary functions are integrated in specific toll switches. A call requesting the new service is routed to the specific toll switch and treated. This method is called pre-Intelligent Network architecture. The new services implemented by this method include initial Free Dial Service, Credit Call Service, and Facsimile Network Service, etc.

This architecture can considerably reduce the number of switches to be modified. Consequently, the problems above stated in case of the implementation by local switch can be resolved. However, the new problems come up such as new circuits need to be established between the local switches and the specific toll switches. More over, the optimum routing is not guaranteed because the calls requesting new services must be routed to the specific toll switch regardless of the final destination.

3.3 INTELLIGENT NETWORK

In order to overcome the problems in pre-Intelligent Network and to seek more effective architecture for future various services, Intelligent Network has been proposed and implemented. In this architecture, the advanced functions are separately implemented in intelligent nodes independent of actual switching nodes.

In NTT's Intelligent Network, there are two typical kinds of intelligent nodes: NSSP (Network Service Support Point) where network management functions such as database access and service management are implemented, and NSP (Network Service Control Point) where service control functions are implemented. As a result that each local switch accesses directly to NSP, the optimum routing is attained.

Intelligent Network enables a network operator to easily provide advanced services simultaneously in a nation-wide area. The new services implemented by Intelligent Network architecture are as follows:

-Free Dial Service (in service)
-Dial Q (in service)
-Credit Call (in service by pre-IN, planned to be changed to IN architecture)
-Closed User Group (awaiting service-in)
-Private Numbering Plan (awaiting service-in)
-Virtual Private Network (awaiting service-in)
-Mass Calling Service (under development)
-Personal Communications Service (under development)

4. INTELLIGENT NETWORK TECHNOLOGY

The technology required to create advanced telecommunications services can be divided to the following three major elements.

4.1 DIGITAL SWITCHING SYSTEM

-D70 (NTT's digital local switching system)
-Connection processing
-Service identification
-Access to NSP

4.2 COMMON CHANNEL SIGNALING No.7

-STP (Signal Transfer Point)
-ISUP (ISDN User Part)
-TCAP (Transaction Capability Application Part)

4.3 INTELLIGENT NODE

-NSSP
  Data base management
  Service specification compilation
  NSP management
  Customer Access management

-NSP
  Segmented functional part
  Real time service analysis and control
  Customer data management

5. BASIC NETWORK FUNCTIONS

It is very important to allocate strategically the segmented functions to network nodes for the rapid and flexible provision of advanced services. Those basic network functions are as follows:

-Dialed number conversion
-Charging
-Connection processing
-Network information transfer
-Customer control
-Network operation and management

6. CURRENT IMPLEMENTATION

The current NTT's Intelligent Network is shown in Figure 3. The intelligent nodes such as NSP and NSSP are completely independent of their locations. Therefore, they can give the flexibility and freedom to data allocation and operation.

In NTT's network, NSP has the access to the Traffic Control System (TCS). For example, NSP always counts the number of the busy subscriber lines of a certain customer, and compares it with the total number of subscriber lines. If all the lines are busy, NSP responds to the local switching system (GC) with the order of Busy Tone Treatment. If the number of calls to the same customer increases over the certain threshold level, NSP will judge as the congestion and report the event to TCS. As a response, TCS will send all GCs the order not to access the NSP for the service request of the concerned terminating customer. This traffic control enables the effective use of network facilities because of the reduction of invalid calls. It is also very important in order to protect the network from the peak traffic to a certain customer.

Presently, the new method of function allocation is under development to meet the demand of mass traffic such that telemarketing customers want to handle thousands of calls simultaneously. In the new Intelligent Network architecture, the necessary functions and customer data will be down-loaded from intelligent nodes to GC. After that, GC can handle those calls in the same manner as NSP. This new method will be able to release NSP from the congestion due to the access by mass traffic. As a result, considerably many calls can be handled at the same time.

7. SERVICE EXAMPLES

The major services implemented or under development using Intelligent Network architecture will be explained in terms of the following points.

-Transition from the existing analog network
-Administration of busy or vacant subscriber lines
-Mass traffic processing method
-Personal Telecommunications Service

8. TOWARDS FUTURE ENHANCEMENTS

The Intelligent Network and advanced services have been developed on the existing network. Therefore, there are still important issues to be solved for the future perfect Intelligent Network. The major issues are as follows:

-Customer Control
  Provision of "Tailor-made" customized services not "Ready-made" services
-Operation
  Provision of service operation and area-free operation
-Management and Administration
  Enhancement of billing processing
  Provision of ample traffic information

A Personal Secretary for Everyone

Henry Hoeksma, Hugh Bradlow, John Myers, and Kamyar Emami
NorTel Technology Centre
Wollongong, Australia

1. Abstract

The combination of powerful personal computers and advanced modern telephone exchanges provides an opportunity to enhance personal telephone services through personal computer applications. In this paper we describe an exploratory system which enables a personal computer to be used to emulate a personal secretary in the handling of incoming calls for a knowledge worker. The paper provides an analysis of the role of a personal secretary and describes how the computer based system provides equivalent functionality.

2. Introduction

Businesses are continuously seeking ways of improving the productivity of their knowledge workers. Personal assistants or secretaries would help accomplish this goal, but this type of support staff has a high and recurring cost which increases each year.

The advent of the personal computer has greatly reduced the dependency upon support staff by enabling office workers to perform by themselves a number of functions which previously required the assistance of such staff. These include letter writing, filing, copying documents, mailing, business planning, and presentation preparation. (The computer-assisted incarnations of these functions are word processing, databases, laser printing, electronic mail, spreadsheets, and graphics programs.)

The "quantum leap" that the personal computer has brought to the workplace is now being expanded to include the telephony aspects of an office worker's job function. Despite many advances, there are still telephony functions which distract knowledge workers from their prime goals and with which a personal secretary can provide invaluable assistance. We have analysed these telephony related functions of a personal secretary and discovered that nearly all of them are within the capabilities of a typical personal computer and modern telephone exchange.

3. Enabling Technologies

It has long been recognised that a more powerful user interface would enable telephone users to gain increased utility from the powerful and complex features offered by a modern digital exchange. The use of a graphical user interface on a personal computer provides an attractive means of achieving this. Furthermore, personal computers provide the computational power, permanent storage, and access to peripheral devices that enables them to be the preferred platform for enhanced personal telephone services.

The powerful common channel signalling access offered to telephone users by modern exchanges makes possible the creation of a range of personal computer applications which offer the user flexibility and ease of use. The prime examples of this type of signalling are the D channel signalling protocols offered by the ISDN as well as many PABXs and key systems. In addition to basic telephone service, such protocols offer information about the calling party (calling line identification, or CLID) and allow the subscriber to control the disposition of the call through features such as call forward, transfer, and conference.

The implementation of telecommunications applications on the personal computer thus requires a means of connecting the D channel signalling on the exchange line to the computer. This connection requires custom hardware and software which is dependent upon both the architecture and interfaces of the computer and upon the protocols offered by the telephone exchange. The

hardware bridge may be provided by a plug-in board for personal computers (using the NuBus, MCA, ISA, EISA, or other buses) or through an external device which is connected to the personal computer via a standard data interface (such as SCSI, RS-422 or RS-232C). A block diagram of the latter configuration is shown in Figure 1.

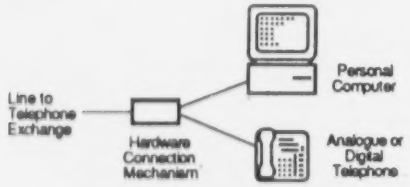

Figure 1: Connection Arrangements

Considerable additional value is achieved if this same connectivity mechanism is used to bring the ISDN B channels (or PABX equivalent) into the computer, since this broadens the range of the telecommunications applications that can be offered. First, it allows data communications applications to use the switched connections offered by the telephone network, and second it allows digitised voice to be brought in and out of the personal computer. The latter offers considerable value for telephony applications since it enables the application to play prompts to and record messages from callers. It also allows the telephone to be connected to the computer and to be used as a microphone and a private loudspeaker for a variety of multimedia applications.

Our research has shown that the computer system required to implement telecommunications oriented applications, such as the one emulating the functionality of a personal secretary, does not need to be particularly powerful. Interfacing with the D channel signalling protocol does not place stress even on low end computing systems, since an information rate as low as 300 bps will suffice. The most demanding requirement is bringing the voice stream into and out of the computer. The voice stream represents a relatively high information rate and must be read from and written to disk in real-time to avoid artificial constraints on the duration of the voice which may be played or recorded. Since current personal computer operating systems are not designed for real-time processing we have found this to be a demanding aspect of the software system design. Nevertheless, our research has shown that many current models of Apple Macintosh™ and IBM™ compatible computers are sufficiently powerful to execute B plus D channel applications in real-time.

4. The Secretary's Role

In a modern office, a typical secretary's job function includes much of the administrative and organisational work needed for the day-to-day running of the office. This may include requesting information or quotations from vendors, ordering and stocking of supplies, and maintaining schedules for visits and meetings. All of the above tasks require the use of a telephone.

Associated with these high-level job functions is a set of telephony related operations which are independent of the function itself. For example, answering a call, determining whom it is for, and transferring the call to the appropriate number is independent of what the call is about.

The secretary performs many of these telephony related operations on behalf of the knowledge worker. Since the secretary often does not need to know the reason for or contents of the call, these operations are open to automation on existing personal computers without the need for artificial intelligence techniques.

The operations performed by a secretary which involve a telephone can be usefully separated into incoming and outgoing call handling. We have concentrated our analysis on incoming call scenarios as computerised assistance with outgoing calling has already been developed into products such as Northern Telecom's *Meridian TeleCenter™* for the *Meridian 1™* PABX.

The purpose of having a secretary handle incoming calls is to allow the knowledge worker to concentrate on his/her work with a minimum of disruption. Based on instructions given to the secretary by the knowledge worker, the secretary decides how to handle each call.

The operations performed by a secretary on an incoming call always begin with:

- *Identifying the Caller*. This may be done via CLID display on the telephone, recognition of the caller's voice, the caller announcing his/her name, or the secretary asking who the caller is.

- *Screening the Call*. Based upon who the caller is and upon the current location and status of the

knowledge worker (for example, "in a planning meeting in room G17"), the secretary determines what further action to take.

Several possible actions may then be taken by the secretary:

- *Giving Information.* If the call can be handled by the secretary, such as when the call is from someone whom the knowledge worker has left information for but does not wish to speak with, then the secretary gives the caller the information and releases the call.

- *Transferring the Call.* If the call is best handled by someone other than the knowledge worker the call is transferred to the appropriate person or department.

- *Taking a Message.* If the knowledge worker is not available or does not wish to be disturbed the secretary takes a message.

- *Connecting the Call.* If the result of the screening is that the knowledge worker should be alerted to the call, the secretary puts the call through to the worker. The information collected during the screening process is often passed on to the knowledge worker.

A special type of incoming call occurs when the knowledge worker is away from the office and calls in to speak with his/her secretary. While some of the above actions are still valid, other actions may also be performed.

- *Delivering Messages.* The knowledge worker may ask to have new messages read to him/her by the secretary.

- *Dialling Numbers.* The secretary may dial a number for the knowledge worker and then connect the worker to the called line.

- *Updating the Worker's Location.* The knowledge worker may tell the secretary what his/her current location is so that future incoming calls may be connected to a telephone at that location.

- *Updating the Call Screening Rules.* The knowledge worker may also tell the secretary that he/she is now willing to accept calls for which messages were being taken, or that he/she is now busy and that more calls should be blocked.

5. The Computer as Secretary

Many knowledge workers have today a personal computer which sits on or beside their desks and which is for their exclusive use. Currently these computers run programs (such as word processors and spreadsheets) which perform actions only on the direct command of the knowledge worker.

As the speed and capacity of a typical personal computer increases it becomes practical for the computer to act as an agent on behalf of the knowledge worker. The earliest examples of this are electronic mail systems which collect mail and notify the knowledge worker of the existence of new, unread messages.

If the computer is connected to a telephone system with certain capabilities (see §3), then the computer may act as a personal secretary agent for the handling of incoming telephone calls.

5.1 Building a Secretary

Our approach to providing a personal secretary agent is to define a set of building blocks, called services, which correspond closely to the telephony operations discussed earlier. A *computer-secretary* is then a collection of services which are linked to one another so as to provide a sequence of actions which may be applied to a call. Any service may be linked to any other service, and some services may have several branches. A call transfer, for instance, may link to different services depending upon whether the line transferred to is busy, does not answer, or answers.

Collections of services may be organised into service profiles to be followed by the computer-secretary. Such profiles define the paths which may be taken by the secretary on each possible type of incoming call.

The knowledge worker, hereafter called the owner, may then configure his/her computer-secretary by creating service profiles. For example, a service profile for weekends may just direct all calls to a message taking service, whereas a profile for "do not disturb" during

working hours on weekdays may specify a more complex chain of services:

- If the owner's manager is calling, then ring the owner's telephone up to three times. If the owner does not answer, then take a message (with a special greeting for the manager) and release the call.
- Otherwise, transfer the call to a co-worker. If the co-worker is busy or does not answer, then take a message (with a general greeting) and release the call.

5.2 Services

The profiles can identify the caller, make screening decisions, and then give information, transfer the call, take a message, release the call, or connect the caller to the owner. If the caller *is* the owner, the computer-secretary may also deliver messages, dial numbers for the owner, and accept changes to its configuration.

5.2.1 Call or Caller Identification

Incoming calls may be identified in much the same way that a human secretary identifies the caller. If the exchange supports CLID for at least some calls, then this information may be used: If not, the computer-secretary may ask the caller for his/her name (if speaker identification software is available) or for a personal identification number (PIN) which the caller then enters via the DTMF keypad on his/her telephone. The latter two techniques are superior in that they identify the *caller* rather than the *telephone*, but they are also more obtrusive.

Whatever information is available may then be enhanced via searches of on-line directories. For example, if the CLID is known, a search of the organisation's on-line directory will produce the caller's name and department.

5.2.2 Call Screening

Screening consists of using the caller's identity, the called number (where the owner has more than one line), the day, date, and time, whether the incoming call is internal or external (for PABX implementations), plus any other instructions about the owner's status (such as "I'll be at lunch from noon until 2:00 PM today.") to make a decision on how to handle the call.

The result of the screening is that the call is linked to another service (or chain of services) which handles the call appropriately.

5.2.3 Announcements and Voice Menus

Two services which implement the secretary's role of providing information to callers are the ability to play announcements and the ability to provide a menu of choices to be selected by the caller. When combined, these services allow the computer-secretary to handle some types of calls entirely on its own.

An announcement is a pre-recorded message for callers. It may be used to tell callers when the owner will be available, the names of colleagues who may be able to help, a project status report, or any other information the owner wishes to make available.

A voice menu presents the caller with a list of choices which may be selected by entering DTMF digits. In this way a caller may be given a choice of services. If the services chosen by the caller do not include an attempt to connect to the owner, then the owner need not be involved in the call.

5.2.4 Call Transfer

This service transfers the call to another number. If the computer-secretary can detect that the number to be transferred to is busy or does not answer after a specified time, the call may be linked to another service. If the transfer is successfully completed the computer-secretary drops out of the call.

If the owner is at his/her desk the computer-secretary can ring the owner's telephone directly. Connection to the owner requires transferring the call if the owner is at a remote location.

5.2.5 Message Taking

Messages may be taken from the caller primarily by asking the caller to leave a voice message. The message may be recorded either directly onto the personal computer or onto an external voice mail system.

The former approach has the advantage of supporting a graphical view of the voice (for direct selection of the playback position) but also the disadvantage of using significant disk space on the owner's computer. Although the owner can specify an upper limit, the actual amount of space used is determined by the

callers in how long they talk and how often they call, rather than by the owner of the computer.

Recording messages onto an external voice mail system has advantages if there is already an existing system in place and if it is desirable to remotely retrieve messages even when the owner's computer has been turned off. In practice, it is believed that the two systems will complement one another.

5.2.6 Message Retrieval

If an external voice mail system is being used to store messages from callers, then the computer-secretary need not be involved in their retrieval. The owner would call the voice mail system directly.

If messages are being stored on the owner's computer and the caller has been identified as the owner (usually with considerable certainty through either voice recognition or a unique PIN) then message retrieval and other services may be made available.

Such message retrieval is essentially identical in its remote user interface to that of the external voice mail system. The main difference is that because it is integrated into the rest of the computer-secretary, other services may be used before and after message retrieval during the same call. (The *local* user interface would be quite different of course–a window with a list of messages which may be selected and played.)

5.2.7 Remote Dialling

Another service which is usually made available to just the owner is the ability to dial numbers from a remote telephone as though the secretary were placing a call for the caller. The computer-secretary accepts the number to be dialled through DTMF key-presses or through voice recognition. It then puts the caller on hold, dials the collected number, and if the call succeeds, joins the caller with the dialled line. The computer-secretary may drop out of the call at this point or may wait silently in the background until needed to perform other services.

Remote dialling, especially with enhancements for name dialling and for restricted access to toll trunks, is also useful as a general service for any caller. (Name dialling uses a directory to determine a number from a name, using the letters on the telephone keypad to spell out the name.)

5.2.8 Reconfiguration

A service which is always reserved exclusively for the owner is the ability to reconfigure the computer-secretary. Reconfiguration includes changes to the call screening rules and the ability to turn the computer-secretary off. The owner may also indicate his/her current location (that is, current telephone number) to the computer-secretary so that future calls may be connected to the owner at a remote location.

6. Computer-Secretary Advantages

The computer-secretary is intended for those knowledge workers who would not be provided with a human personal secretary because of the high cost. Any assistance with call handling is therefore an improvement for these workers. Additional advantages arise from the high availability of the computer-secretary and from the non-centralised nature of its administration.

Since a computer may be operating during nights, weekends, and other holidays, the services of the computer-secretary are always available. This universal availability can be used in novel ways, such as in a precursor to Universal Personal Telecommunications (UPT) services. The owner may use a single telephone number for all voice oriented communications, and the computer-secretary at that number can then find the owner. With the additional capability of remotely reconfiguring the computer-secretary, the total service being provided closely parallels the capabilities proposed for UPT.

Because our exploratory system is a personal one, centralised administration is not required. Although current PABXs provide some of the desired computer-secretary functionality through call forwarding, Direct Inward Service Access (for remote dialling), and voice mail, these functions require centralised purchasing and administration. A computer-secretary allows, for example, transfers which are more flexible than PABX based call forwarding (in that they may be chained in any order, and with separate actions for busy or non-answering extensions) yet allows all purchasing, configuration, and administration to be done by the owner without assistance.

In summary, our analysis of the telephony operations of a personal secretary has shown that most of these operations can be automated on typical personal computers. In organisations which cannot currently afford human secretaries for the majority of their knowledge workers, the computer-secretary may provide a cost effective solution.

The Deployment of Fiber Optic Systems and The Technology

TAKANORI UMAYAHARA, Executive Engineer
TETSUYA FUNABASHI, Senior Engineer
KIMIHIDE JINNO, Senior Engineer
KENJI MISU, Engineer
NTT Network Systems Development Center, Tokyo, Japan

1. ABSTRACT

The deployment of optical fiber systems and the technology required for this deployment are two of the most important issues confronting telecommunications carriers as they approach the 21st century. This paper will describe the FTTZ (Fiber To The Zone) part of NTT's nationwide deployment strategy. It will also introduce new technologies necessary for the realization of FTTO (Fiber To The Office), FTTZ and FTTH (Fiber To The Home). In addition, it will take a look at NTT's "Chiyoda Pilot Plant", a model plant employing optical access systems.

2. THE ROLE OF FIBER OPTIC SYSTEMS

In Japan, optical fiber systems are seen as a key step toward relieving Japan's heavily congested underground facilities. Fiber optic cables will also be installed in large newly developed areas, and will replace old crossbar switches in rural areas. Moreover, optical fiber systems are necessary to support growing user demand for such high-speed and broad-band services as high-speed digital leased circuit services.
NTT regards the deployment of optical fiber systems both as the foundation of Japan's future communications infrastructure and as the key to realizing NTT's service vision for the 21st century, which is based on providing Visual, Intelligent and Personal services. Accordingly, NTT is now introducing optical access systems into urban office buildings. This process, called Fiber To The Office (FTTO) is the first stage in NTT's deployment plan. The next stage, Fiber To The Zone (FTTZ), is being planned as an intermediate step to the third stage, Fiber To The Home (FTTH) and also to the FTTO in certain areas.

3. DEPLOYMENT OF OPTICAL FIBER SUBSCRIBER-LOOPS

The replacement of Japan's existing wire cable subscriber networks with optical fiber will evolve in various ways, depending on each area's characteristics. Several network deployment strategies have been devised, such as FTTO, FTTZ and FTTH, in order to make the complicated transition to optical fiber networks as smooth and cost effective as possible.

3.1 FTTO

In urban commercial areas, several types of Central Terminal/Remote Terminal (CT/RT) systems are now being introduced to big office buildings as a first step in the FTTO process. Newly constructed buildings are the main deployment targets in this first stage. In addition, FTTO includes introducing optical fiber to existing buildings to relieve the congestion in underground facilities and replace old metallic cables.

In order to accomplish a gradual expansion of fiber optic systems, the next FTTO step will be to provide optical access systems to medium and small-size buildings. Once FTTO has been accomplished, NTT will be able to provide not only low-speed services but also high-speed and broad-band services whereever demand appears.

3.2 FTTZ

In non-business and suburban residential areas, there is now little demand for FTTH, mainly because subscribers do not yet have a clear idea of what type of services will be available and what benefits will result. Although the hardware cost of optical fiber systems are generally more expensive than conventional metallic ones, installation costs are lower in some cases. For example, fiber optic cables can be installed in existing underground facilities relieving the congestion of metallic cables, while new tunnels would have to be built to house new metallic cables. Moreover, the installation of optical fiber systems in newly developed areas will be economical in the long run because subscribers are expected to increase rapidly in such areas. Thus, the introduction of optical fiber systems will result in reduced reconstruction costs and enhanced telecommunications networks, and will enable NTT to meet projected future demand for advanced services.
As a preliminary stage to FTTH, NTT plans to first promote the introduction of optical fiber systems to certain zones within an economically advantageous range, which is called FTTZ (Fiber To The Zone). Here, "Zone" means the area in which subscribers receive services through CT/RT systems. The number of subscribers in one "Zone" ranges from a few dozen to about 1000.
Under FTTZ, metallic cables are extended from an RT to a user, as shown in Figure 1. At present, NTT is planning the development of smaller-size RT systems which can be more economically implemented. Such RTs will result in the expansion of optical fiber to each floor of buildings and places close to subscriber homes. In this way, initial subscriber demand for B-ISDN services can be easily met by connecting a spare fiber to the existing optical fiber cables installed near user homes.

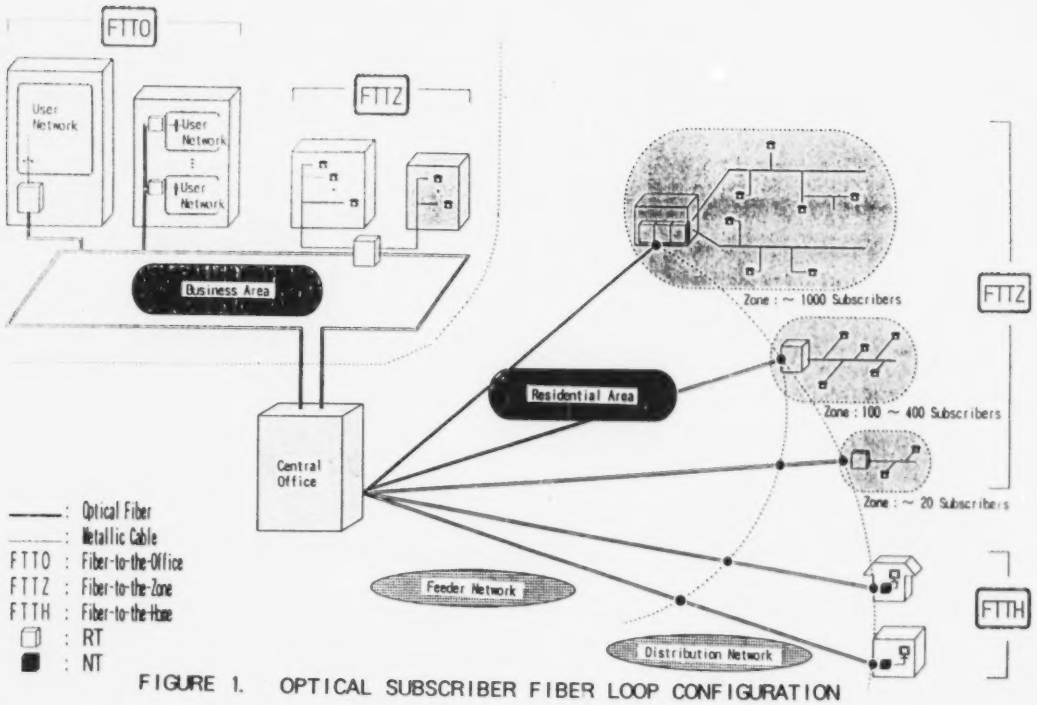

FIGURE 1. OPTICAL SUBSCRIBER FIBER LOOP CONFIGURATION

For FTTZ to be successful, it will be necessary to develop technologies that will enable RT systems to serve as platforms for supplying optical fiber systems to users. In particular, RT system installation must be more flexible, and service capacity must be expanded.
The deployment of optical fiber systems will follow several scenarios, depending on the characteristics of each area. Figure 2 shows NTT's deployment scenarios for optical fiber systems.

4. TECHNOLOGIES FOR OPTICAL FIBER SYSTEMS

NTT has developed a new CT/RT system and a Subscriber Line X-connect Module (LXM) system in order to realize a more economical and efficient introduction of FTTO and FTTZ.

4.1 NEW A/I-CT/RT SYSTEM

The new CT/RT system, as shown in Figure 3, can provide both analog telephone services and ISDN basic rate interface services using technologies established in the previous model. This system is both more compact and cost-effective than the previous one, and can be installed in user buildings and portable telephone offices.
Two system types have been developed with differing capacities. One type accommodates 100 subscribers and is installed in medium-size user buildings. The other handles 400, and is installed in large-size user buildings as well as portable telephone offices and boxes. Both types of RT systems consist of RT multiplex, testing equipment, subscriber-circuits, a power supply circuit and battery equipment.

These systems are mainly installed in the MDF rooms of user buildings. The 100-subscriber model sits in a cabinet measuring H700mm× W700mm × D450mm and is small enough to be set on the floor. It is powered by commercial AC100 Volts. If commercial power should fail, both systems can operate for up to three hours on their own battery power.

4.2 LXM SYSTEM

4.2.1 BACKGROUND

NTT's LXM system, currently under development, has been designed to help bring about the realization of FTTO and FTTZ, particularly in large-scale business areas. The LXM will help facilitate the deployment of optical access systems.
The LXM enables NTT to meet user demands, for example, by realizing efficient risk distribution. At present, most subscribers in large-scale buildings require risk distribution. That means each subscriber has to be accommodated by plural local switches. However, this has not always been possible, because plural RTs when set on a floor occupy a large space. In addition, users also wish to retain their telephone numbers when they move. In order to meet these requirements, each subscriber accommodated by one RT must be able to connect to whichever switch is available. The LXM makes this distribution possible. Moreover, the LXM also enables efficient use of switches. For example, some of ISDN subscribers are now accommodated by local switches (D70) which distribute them to ISMs (I Interface Subscriber

Module). Accordingly, the LXM will distribute ISDN subscribers directly to ISMs and save the accommodating capacity of DTOs.

4.2.2 CROSS-CONNECTING PER 64KB/S

The LXM's feature characteristic, the cross-connecting function, has a minimum cross-connecting unit of 1 time slot (64kb/s). This enables the LXM to handle cross-connecting for each subscriber.
NTT is developing the LXM with reference point V, which is the point between the optical access system and switch. The function of 64kb/s cross-connecting gives the LXM an inner-structure which is compatible with coming standardization of the reference point V. In addition, the LXM is able to cooperate with various kinds of testing signals, controling signals and ISDN interfaces by defining transmission formats. The 64kb/s cross-connecting makes the LXM flexible in terms of adapting to new interfaces.

4.2.3 LXM CHARACTERISTICS

The LXM will be located in an NTT central office and will be positioned between the RTs and local switches. Thus, subscribers accommodated by RTs will be connected to local switches through the LXM. Figure 4 shows the LXM characteristics.

(1) Distribution of Analog/ISDN subscribers
The new A/I-RT accommodates both analog and ISDN subscribers. The LXM divides them and distributes analog subscribers to DTO switches and ISDN subscribers to ISMs (I Interface Subscriber Modules).

(2) Distribution of subscribers to switch
LXM can distribute a subscriber to any local switch connected to it. This characteristic enables efficient risk distribution and allows subscribers who move within a defined area to retain the same telephone number.

(3) Operation systems interface
LXM is connected to operation systems through Op-LAN (OPeration-LAN) as well as other network equipment. And, with the LXM and the robot-controled MDF, telecommunications network operations will be more efficient. For example, operators can automatically and sequentially execute such operations as making a new subscriber telephone available.
NTT will introduce the LXM and other equipment at a big model plant and put them into service in the spring of 1993. Details of this plant are discussed in Chapter 5. NTT is also planning to develop a smaller LXM for smaller telephone offices in urban areas.

5 A Deployment Challenge

NTT is planning to establish a large-scale model plant with optical access systems including LXM. This plant will be put into commercial service to demonstrate how telecommunications services will develop in the 21st century. This will also provide a platform for future strategic NTT offices in which total operation systems and optical access systems will play important roles.
This chapter focuses particularly on the significance of introducing optical access systems. The technologies introduced in the plant will represent the key technologies for the promotion of FTTO and FTTZ.

5.1 Chiyoda Pilot Plant

NTT is now constructing the model plant, called the "Chiyoda Pilot Plant", at Chiyoda ward in Tokyo. This plant will replace the Chiyoda Plant Center, which now accommodates about 80,000 subscribers.
The Chiyoda area is Japan's main financial district and is one of the three biggest financial centers in the world. Accordingly, to remain competitive, there is a constant need in this area for the most modern and advanced telecommunications services. The Chiyoda Pilot Plant is expected to begin providing such services from the spring of 1993. This will lead to the following benefits.

(1) Establishment of a basic infrastructure for future optical fiber subscriber-loop systems.

(2)Higher quality telecommunications services including faster response to user demands.

(3)More efficient NTT management of telecommunications services

Initially, four courses of a loop-shaped optical cable will be installed, each formed by 1000 single-mode optical fibers. Then, by the year 2000, optical access systems will have been introduced into all of the approximately 110 office buildings in the area.
Almost all telecommunications equipment, except for subscriber-loops, will be assembled in the NTT center. This includes all switches, the LXM, the robot-controlled MDF, the Central Terminal, total operation systems and so on. Using these facilities, the Chiyoda Pilot Plant will provide a glimpse of Japan's future telecommunications infrastructure.

6 Conclusion

FTTO and FTTZ must be deployed in cooperation with existing systems. Before FTTO and FTTZ can be successfully realized, it will be necessary to develop a more economical optical access system and more efficient total operations systems.
New systems now under development, such as the LXM and the new CT/RT system, will become part of the basic infrastructure of FTTO and FTTZ. These new systems will be evaluated at the Chiyoda Pilot Plant. Experiences gained from the pilot plant will enable NTT to develop optical fiber subscriber-loop systems to assure the successful realization of FTTO and FTTH.

"VISTASAT"

An All Digital Small Earth Station For Rural Communication Services

Stuart P. Browne, Product Manager,
SSE Technologies, Inc.
California, USA

ABSTRACT

Rural development in Asia and the Pacific frequently depends on satellite communications networks to link villages to regional and national centers. The SSE "VISTASAT" earth station uses all digital transmission technologies which are superior to the older analog companded FM-SCPC systems and provides bandwidth and power efficiency that results in the user gaining access to lower cost "resource based" satellite tariffs.

1.0 Introduction

In the 1990's, reliable and highly interconnected telecommunications networks are recognized as one of the fundamental infrastructures needed to support a successful national economy. In newly developing countries, satellite communications is clearly the most cost-effective and fastest way to bring toll quality telecomms service to rural villages and remote subscribers. Because of critical cost and time considerations, satellite communications based telecommunications networks for international and domestic long distance service are being implemented in all parts of the globe.

The Pacific Rim in particular has seen a rapid rise in the application of satellite communications to meet network development needs. Throughout the ASEAN region, Indonesia's Palapa satellite system is successfully providing domestic and international telecom links and television service to cooperating countries. In Thailand, the government selected satellite communication over terrestrial systems to link rural villages to the national telephone network via ASIASAT. In adjacent Laos, the capital city of Vientian recently became linked to the switched international long distance network by eight INTELSAT "VISTA" Service circuits. Out in Oceania, the island nations of the Southwest Pacific, are now being linked by INTELSAT's "Super VISTA" Demand Assigned Multiple Access (DAMA) service to a full mesh network of domestic and international earth stations.

To facilitate the even wider useage of satellite communication networks, SSE Technologies has developed a low-cost, multi-channel digital earth station for use with the worlds commercial communications satellite systems. Called, the SSE "VISTASAT", this two-way satellite terminal uses an advanced microwave radiolink system , modular solid state electronic components and digital transmission technology to provide network operators with a versatile way to connect telephone trunks, synchronous data, or digital video for public switched or private line networks.

2.0 The VISTASAT Earth Station

SSE Technologies, Inc., the US manufacturer of Advanced Small Aperture Satellite terminals (called ASAT's), has developed an integrated satellite radio transceiver, digital modem/multiplexer package for use with "thin-route" network services like those offered by INTELSAT's VISTA and INTELNET Service tariffs. Dubbed "VISTASAT"®, this complete earth station package can supply toll quality digital voice, Group III fax and synchronous data communications via digital satellite circuits from 9.6 kbps to 64 Kbps. The SSE VISTASAT is designed for operations in point-to-point, STAR and Full Mesh networks.

2.1 Technical Description

The VISTASAT earth station was designed to take advantage of a number of convergent electronic technologies to produce systems that are highly reliable, low in cost, easy to install, maintain and operate. Importantly , they provide network operators with an all digital satellite terminal so as to take full advantage of the low priced "resource based " satellite tariffs being offered by INTELSAT and other satellite common carriers.

SSE Technologies accomplishes these design goals through the application of solid state devices in the Radio Frequency (RF) ASAT, by manufacturing it's earth station products in a modular package that enables graceful systems upgrades to higher power and data rates, by incorporating digital transmission technology for error correction and bandwidth compression, and by using small antennas with the RF terminal. The result is an integrated earth station system that provides the bandwidth and power efficiency needed in modern Single Channel Per Carrier (SCPC) satellite networks.

237

The VISTASAT earth station is designed around SSE's standard ASAT RF product line. ASAT's incorporate Internally Matched Field Effect Transistors (IMFET) in the Solid State Power Amplifier (SSPA) providing highly stable power and gain with minimal intermodulation distortion. The ASAT downconverter incorporates low-noise High Electron Mobility Transistors (HEMT) as well as Gallium Arsenide Field Effect Transistors (GaAsFET) to provide a systems noise temperature as low as 45° Kelvin at C-Band and 160° Kelvin at Ku-Band. Frequency synthesizers are referenced to an ovenized 10 mHz. crystal oscillator providing fully synthesized frequency selection . Figure 2-1 shows the basic SSE ASAT consisting of a microwave "driver" unit (or transceiver, solid state power amplifier unit (SSPA), low noise block down converter (LNB), power supply unit(PS) and interconnecting cables.

The SSE ASAT operates in the following manner. On the transmit side, the RF driver upconverts a 70 or 140 mHz. Intermediate Frequency (IF) from the modulator to a radio frequency in the 5925-6425 mHz. (C-Band) or 12-14 mHz (Ku-Band). The transmitter configured for either fixed gain block or automatic level control (ALC) drives the solid state power amplifier with 8 dBm with the signal being amplified to the appropriate power output level (2, 4, 10, 20 watts at C-Band or 2, 4, 8 or 16 watts at Ku-Band) at the 1 dB compression point.

On the receive side of a C-Band system, the LNB downconverts the satellite downlink frequencies in a "block" to a L-Band frequency (1 gHz.) which is then fed to the RF driver unit for further downconversion. Downconversion modules include a transmit reject filter, a LNB and a downconverter module. The LNB is referenced to an agile synthesizer, and the downconverter is referenced to a Fixed Frequency Loop (FFL). See Figure 2-1 *ASAT Terminal Block Diagram.*

SSE ASAT's have been installed in 46 countries by systems integrators, PTT's and network service providers who typically have only purchased the ASAT RF package from SSE. The successful implementation of thousands of the SSE ASAT's have established the product as an industry standard.

In 1991, SSE began manufacturing digital satellite modems as a complement to the ASAT RF products. Integration of digital multiplexers and antennas quickly followed. Now a fully factory tested integrated earth station package consisting of an SSE ASAT with solid state power amplifier, SSE digital satellite modem, digital multiplexer and antenna are being supplied to customers. Factory systems integration insures compatibility of electronic interfaces and optimized transmission characteristics.

Requests by budget conscious customers for a "thin-route" earth station package resulted in the VISTASAT terminal products birth in early 1991. Designed with modularity and upward compatibility in mind, the VISTASAT follows with the SSE's "modular concept". This successful concept enables users of SSE ASAT's to upgrade to higher power levels without replacing the ASAT driver or LNB.

As an extension of this modular concept for the ASAT equipment, the possibility of producing fully integrated earth stations capable of being "grown" from a basic two location point-to-point network, to a STAR network cluster of ten to twenty sites handled through a "mini-hub", to a wide area full-mesh DAMA network of hundreds of sites, was seen as fundamental in furthering SSE's modular design concept. The VISTASAT was also designed so that networks could be developed around satellite tariffs that reward bandwidth and power efficient transmission systems with lower monthly channel rates.

Bandwidth and power efficiency are the two key factors with INTELSAT's VISTA and INTELNET service tariffs. With INTELSAT facing international competition from other satellite carriers, the worlds largest satellite network operator has initiated rewards to it's members with low-cost tariffs based on efficient use of the expensive satellite resource. This "resource based" utilization concept emphasizes use of technologies such as digital circuit multiplication and digital demand assignment of satellite channels to accomplish bandwidth efficiency. Use of voice activated, low-bit rate, digital modems for DAMA networks or "on hook/off hook" Pre-Assigned Multiple Access (PAMA) satellite circuits also conserves satellite transponder power.

First offered by INTELSAT in 1984 to stimulate satcom use by the less developed countries, VISTA Service provided an INTELSAT user with low monthly channels rates if companded FM-SCPC using 22.5 KHz.. bandwidths and voice activation were employed along with INTELSAT D1 category earth stations (6/4 gHz., 4.5 meter antenna, G/T of 22.7 dB/K). Because of the high costs of analog earth station products offered at the time, few VISTA circuits were ever actually put into service.

In 1989, the INTELSAT board reacting to members requests, agreed that 32 Kbps digital channels that occupy the same bandwidth as the old analog FM could instead be used in the VISTA Service. The SSE VISTASAT terminal fits the new specification for use in PAMA or DAMA SCPC applications as described in INTELSAT's VISTA and SUPER VISTA tariffs. As an example, a SSE VISTASAT station can carry four "toll quality" voice channels, "inband" modem traffic at 4.8 Kbps , synchronous data at 19.2 and Group III Fax. TV receive only capability can also be easily added. Cost per a single circuit are $445 per month for a preemptible channel or $780 per month for a non-preemptible channel, providing

an extremely economical way to bring telephone services to rural areas. Modular components and "low tech" equipment mounting kits enable a VISTASAT terminal to be installed on average in two days. See Figure 2-2 *An INTELSAT D1 Compliant VISTASAT.*

Recently, INTELSAT has suggested moving away from the VISTA Service tariffs because they have been under utilized. Instead, INTELSAT has been suggesting use of it's INTELNET tariff which allows for very flexible technical standards with no restrictions with respect to antenna size, G/T or modulation technique. INTELNET Service may be leased in bandwidth units from 100 kHz to 72 mHz. on either a full time or occassional use basis. Cost savings with the INTELNET service become readily apparent when a 3.8 meter antenna can be substituted for the 4.5 meter D1 compatible antenna as required by VISTA Service.

3.0 VISTASAT Networks

VISTASAT earth stations can be configured for point-to-point, STAR and full-mesh network topologies depending on the users requirement.

3.1 Point-to-Point and STAR Networks

In point-to-point or Star network application, the VISTASAT earth stations are linked using full-duplex satellite circuits. In a point-to-point network, two VISTASAT stations are linked by a pre-assigned circuit and generally each stations is of equal antenna size and configuration. In a STAR network configuration, network heirarchy becomes a factor as the hub station in a STAR network uses a larger antenna and often higher power transmitters than the remote sites. Transmission between the remote and a hub can be at various data rates ranging from 9.6 Kbps, 16 Kbps ,32 Kbps or 64 Kbps. Even at these slow data rates, micro digital circuit multiplex systems (MDCMS) in the VISTASAT can derive and transport multiple voice channels, Group III Fax and carry inband data up to 4800 Bps. To obtain power conservation on the satellite transponder, the VISTASAT digital multiplexer employs an "on hook/off hook" feature which only activates the RF carrier when an incoming call is connected to the input side of the mux. When the call is completed the circuit is placed back "on hook" and the carrier returned to an idle condition. While not as power efficient as voice activated demand assignment techniques, this method still results in reduced power consumption on the satellite transponder.

STAR networks using VISTASAT terminals configured as described are ideal for "thin-route" applications such as linking remote villages, mining camps or oil platforms into the switched network often through a so called"mini-hub". Mini hubs are useful as a start-up to a more highly interconnected network topology like demand assignment and can fullfill basic network requirements without large investments in master stations. A typical mini-hub can consist of up to 20 circuits, with each channel permanently assigned to a corresponding VISTASAT terminal. See Figure 3-1 *VISTASAT STAR Network.*

Examples of SSE VISTASAT terminals in STAR networks can be seen world wide. In Europe, they are being used by PTT's to bypass obsolete terrestrial networks left behind by the former Communist operators. In northern Europe they are in service linking North Sea oil rigs to the UK telephone network and in Latin America for a variety of corporate, scientific and government applications.

In Thailand, Indonesia and China, VISTASAT terminals are used in STAR network applications by PTT's and government agencies who, without adequate terrestrial network access, are using ASIASAT and the Palapa satellites to link villages to regional commercial centers. These rapidly developing countries have recognized the benefits of the ease in deployment of VISTASAT's, and the major cost savings over attempting to build expensive terrestrial cable or microwave networks. In the developing world where long system procurement lead times are common and capital budgets limited, many government telephone administrations have decided that they can't wait for fiber optics or ISDN technologies to become affordable. STAR networks using communication satellite technologies are fast becoming the low-cost option to connecting groups of rural subscribers and remote sites into the PSTN.

4.0 Full-Mesh DAMA Networks

When traffic grows in a network, or as more locations are added, the need to move from a STAR network to a "Full Mesh" Demand Assigned Multiple Access (DAMA) network may become an operational requirement. With a full-mesh network any station can connect to any other station through a limited channel pool allocated on demand by a master control station. With DAMA, a Public Telephone administration or private network operator gains tremendous efficiency in the reuse of satellite channels that are shared by a large number of sites. Since channels are assigned on demand as needed, DAMA eliminates the inefficiency of PAMA circuits which may only be used a fraction of the time. DAMA instead concentrates traffic onto a much smaller number of pooled channel resources minimizing bandwidth and using less transponder power.

For DAMA network applications, VISTASAT terminals can be combined with an appropriate DAMA master station controller, digital 16 Kbps modems and remote DAMA contollers to meet the needs of the largest national DOMSAT network. VISTASAT's are now being used in

DAMA networks applications in Europe, and the Far East provided to users by large system integrators and aerospace companies. Using INTELSAT's "Super VISTA" tariffs a network operator can establish a full mesh network for as little as $445 per circuit per month with as few as five circuits being used to link 20 locations depending on traffic. See Figure 4-1 *VISTASAT DAMA Network*

5.0 Model For a Point-to-Point VISTASAT Network

As a network planning tool, it is always necessary to undertake a satellite link budget calculation to determin the satellites EIRP, G/T and Flux density of the downlink signal coming from the satellite in space (the space segment) and the corresponding earth station (the ground segment). When calculated the size of the earth station antenna, power amplifier and noise temperature of the receiver can be made. Assuming the use of INTELSAT V at 174° east, the hemi C-band beam, a point-to-point circuit from the US territory in Guam to Honolulu operating at 32 Kbps rate would require only a 4.5 meter antenna and a 4 watt SSPA. Each VISTASAT terminal would cost less than $50,000 and be capable of carrying four toll quality voice channels. The monthly circuit charge from INTELSAT would be around $500.

6.0 Model For a Star VISTASAT Network

A cost model for a thin-route star network can also easily be developed. This cost model assumes that the network will use INTELSAT V located at 174° east, operate at 32 Kbps and connect nine islands in Micronesia with Hawaii. The satellite link budget indicates that on the hemi-beam, a hub station with a 4.5 meter antenna and a 20 watt SSE ASAT N406 equipped with IF combiner nine digital modems and multiplexer could be used and cost under $150,000. At the remotes in Micronesia, the VISTASAT's would be the same size and power as used in the point to point model. 32 voice channels could be supported between Hawaii and the island locations with "dial tone" being extended from the PSTN in Honolulu.

7.0 Model For a Full-Mesh DAMA VISTASAT Network

If a true Pacific wide multi-site network was to be designed, then DAMA technology would provide the greatest efficiency in terms of satellite channels requirements and earth station costs. In this model, the network will provide the entire Pacific Ocean Region with point-to-point full-mesh capability with high quality, digital, vocoded voice service under the control of a network master station on the Island of Oahu, Hawaii. The master station will comprise a 4.5 meter diameter antenna with the necessary transmission, echo control and DAMA electronics. All of the remote stations will consist of 3.8 meter antennas with similar electronics. The system will be designed for Grade of Service P=0.01. Network operation will utilize the INTELSAT global beam satellite space segment of the IS VA satellite at 177° east. INTELSAT provides the only space segment with global coverage currently available in the POR. However plans by PanAmSat and TongaSat may provide future alternatives. Global coverage must be used for the DAMA point-to-point (remote to remote) to avoid double-hop connections. In this model, 10 satellite channels at $500 each per month would link at least 20 locations across the Pacific with toll quality voice. The master station would cost approximately $250,000 with each remote at under $75,000. If 7000 call minutes per day were carried by the network at a cost of 1.50 per minute, a rapid payback and return on investment for this network would be possible in less than one year.

8.0 Summary

Decades of success stories in developing countries attest to the value of having a reliable national telephone network to support nation building and economic development. To expidite telecomms deployment, public telephone administrations through out the world now recognize satellite communications as the quickest and lowest cost way to bring high quality telecommunications to unserved locations. SSE Technologies, Inc. a pioneer in the development and manufacture of small aperture terminals for voice, data and video is now offering a new version of it's Advanced Small Aperture Terminal (ASAT) optimized for use in digital "thin-route" satellite networks.

The SSE VISTASAT earth station terminal is designed for network operators looking for a fast and cost effective way to bring service to rural and remote areas. Designed as a modular package, the VISTASAT can be configured for a single point-to-point circuit or for use in a network of hundreds of locations. Making use of digital technology and solid state power amplifiers, the VISTASAT provides a user with high reliability, multi-channel capacity at an affordable package price. It also maximizes methods to improve the efficiency of the satellite transponder by using bandwidth compression and power conservation. With the newly advanced "resource based" tariffs by INTELSAT and other satellite carriers now serving the Pacific Ocean region, a satellite based network using SSE VISTASAT digital earth stations can be gracefully and economically expanded as network traffic and topology grows.

A STUDY ON FEASIBILITY OF MOBILE SATELLITE COMMUNICATION SYSTEMS

Kazuyoshi MIYOSHI, Shunichiro EGAMI, Makio TSUCHIYA
Mitsubishi Electric Corp.
Tokyo, Japan

1. ABSTRACT

A concept study was conducted on feasibility of mobile satellite communication systems using the voice codec developed for digital mobile telephone systems. The conclusion seems to be positive.

2. INTRODUCTION

Though mobile telephones have been prevailing significantly, the ground based systems require many base stations and not cost effective in the area where traffic is thin.

In Japan, almost 70% of area has not been serviced. They cover main city areas, trunk roads, so the majority of communication needs of cars are satisfied.

But needs of long range trucks and cars for construction, disaster prevention and security in rural area are not fulfilled enough.

To complement ground mobile communication systems, services using satellites are expected.

Besides cars, boats and rural fixed stations will be served by satellite systems.

Already a low rate message communication system using existing Ku band transponders is servicing in US (Omni TRUCKS).

Satellites with dedicated transponders for mobile communication including voice services will be launched in coming years (Australia, Canada, US and Japan).

In Asia and Pacific region, there are many countries having vast area and it seems that the needs for mobile satellite communication systems will be strong.

Recently, development efforts of low bit rate voice codecs have been conducted extensively and compression technologies having sufficient quality for practical use are being achieved.

A study on feasibility of mobile satellite communication systems using these codecs is shown hereafter.

3. TREND OF VOICE CODEC TECHNOLOGIES[1]

To transmit voice signals in usual telephone quality, a 64 kbps bit rate by amplitude companding and 8 bits PCM is required. But lower bit rates are realized eliminating redundancies of voice signals and the auditory sense. The measures will be categorized in following three methods.

(1) WAVE FORM CODING
Wave forms are kept as much as possible in lower bit rates.

(2) ANALYSIS and SYNTHESIS CODING
Voice consists of voiced sounds which are generated by the vibration of vocal chords and voice-less sounds, by the turbulent flow. Identification of voice sources and voice spectrum are multiplexed and transmitted. In the receiving side, those two informations are demultiplexed and the voice signals are regenerated using a synthetic filter. This is called VOCODER and low bit rates are realized with rather low quality.

(3) HYBRID CODING
Two methods above are combined and fairly good quality is achieved at the bit rate around 10 kbps.

Voice quality of various coding methods is shown roughly on Fig. 1.
Usually MOS (Mean Opinion Score) which is a five level subjective criteria by many hearers is used to show the voice quality.

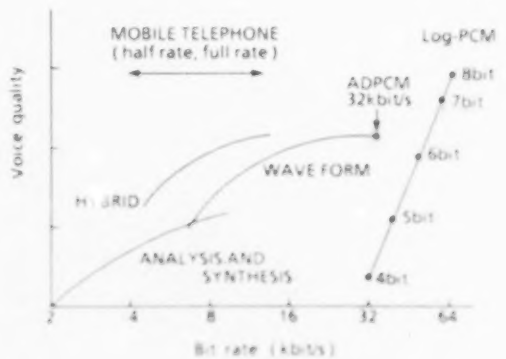

FIG. 1 VOICE QUALITY OF CODEC

VSELP (Vector Sum Excited Linear Prediction) which is a kind of hybrid coding was selected for Japanese mobile telephone systems.

(Voice information	6.7 kbps
(Error correction	4.5 kbps
Total	11.2 kbps

The codec has MOS 3.0 quality at 1% bit error rate [2]. As the next generation, half rate codecs are being developed. Within 1992, the half rate codec for US market will have been developed which has the following rates.

Voice information	4.5 kbps
Error correction	2.0 kbps
Total	6.5 kbps

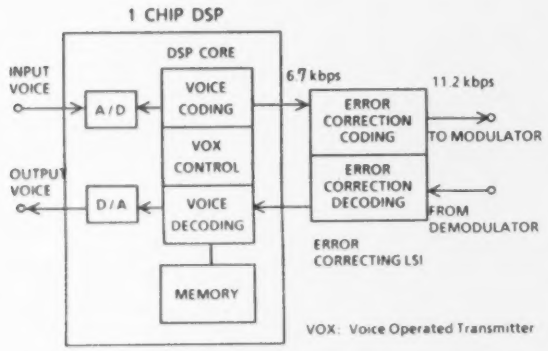

FIG. 2 BLOCK DIAGRAM OF VOICE CODEC

4. SYSTEM STUDY

A total system configuration is shown on Fig. 3.

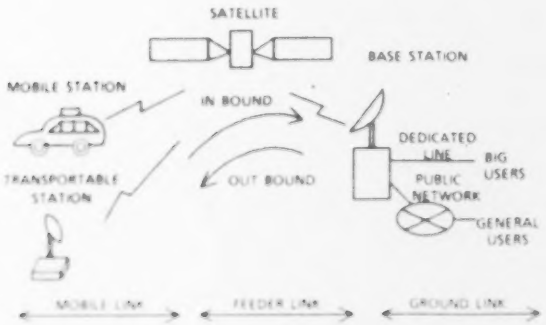

FIG. 3 CONFIGURATION OF MOBILE SATELLITE COMMUNICATION SYSTEM

Big users may use dedicated lines to access base stations. In some cases they will even own base stations. General users will use public networks. The inbound and outbound circuit between a base station and a mobile or transportable station consists a duplex circuit.

In this configuration a communication link between mobile or transportable stations has to pass a base station which means the link will path the satellite twice (2 hops).

This will cause about 0.5 second delay and quality degradations. In this study, only one hop communications are considered (if necessary, two hop communications are realizable though).

When the distance between a user and a base station is large, the ground link expense is high. Then some numbers of base stations will be required to cover wide area.

The ground link expenses will be lowered by multiplexed transmissions of compressed digital voices.

4.1 MOBILE LINK

This is the link between a mobile/transportable station and a satellite. A high gain satellite antenna is required to make a mobile station small.

The high gain satellite antenna leads to narrow antenna beams. This requires multi-beams to cover wide areas.

The multi-beam coverages are easily realized by a multi-port amplifier (MPA) as stated later. The allocated frequencies for mobile satellite communications are L band (1.6/1.5 GHz) globally and S band (2.6/2.5GHz) in the third region (Asia and Oceania).

In this study, S band is assumed avoiding marginal global requirements.

4.2 FEEDER LINK

This is the link between a base station and a satellite. A broader beam satellite antenna will be used for the feeder link because size constraints are not servere for base stations.

The C band frequency is selected as the lowest rain attenuation from C, Ku and Ka bands for fixed satellite communications.

4.3 COMMUNICATION METHODS

A digital communication scheme is selected using the codec which is developed for the ground digital mobile telephone systems.

TDM (Time Division Multiplex) and SCPC (Single Channel Per Carrier) are candidates for multiplexing. In the case of TDM, all earth stations (mobile, transportable and base) have to keep very strict synchronization.

As the frequency width and number of transponders are limited with the mobile satellite communication systems, a transponder may have to be used for various applications.

TDM might constraint the freedom of applications.

In this study the SCPC multiplexing is selected to allow various system configurations in a transponder.

As modulation schemes, BPSK (Bi-Phase Shift Keying) and QPSK (Quadrature Phase Shift Keying) are popular and shall be selected considering effective utilization of frequencies and the ground flux density limitation of a satellite radiated power to avoid interference to the ground radio systems.

The QPSK is selected for this study.

VA (Voice activation) is adopted for outbound circuits to increase the transponder capacity under the power limited condition. The inbound C band transponder has sufficient power and VA is not required.

5. CONSIDERATIONS ON SATELLITE

The EIRP of the MSAT of AMSC and TMI is as high as 55dBW. We assume similar order of EIRP as "state of art".

Following S band parameters are used in our study.

Diameter of antenna	: 3m
Antenna beam width	: 3 degree
Number of beams	: 12 (Fig.4)
Output power of MPA[3]	: 200 W
EIRP (Effective Isotropic Radiated Power)	: 53 dBW
G/T (Antenna Gain/Noise Temperture)	: 5 dB/K

The band width of each beam must be large enough to the required maximum channels of the beam during the satellite life.

The feeder link band width is equal to the sum of band width of each beam.

FIG. 4 MOBILE LINK BEAM COVERAGES
(The coverages are drawn rather arbitrarily)

A base station frequency band is divided for each S band beams. They are converted to a common frequency band and combind by hybrid circuits. All SSPA's have the same inputs and the outputs are devided again separating signals for each S band beams. (SSPA: Solid State Power Amplifier) The MPA has flexibility of traffic allocations for S band beams and partial failures of SSPA's are not critical for any beam.

The feeder link C band parameters are not critical and assumed rather arbitrarily as follows.

Transponder EIRP	: 30 dBW
G/T	: -7^{o} K

The C band antenna may have single or a few beams and beam shapes are not studied yet.

The satellite out bound link is configured as Fig. 5 and in bound link, Fig. 6.

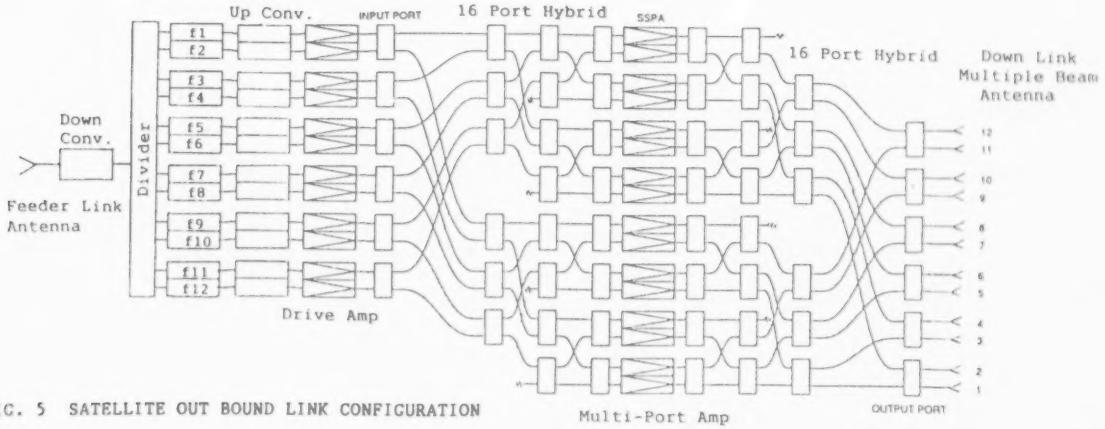

FIG. 5 SATELLITE OUT BOUND LINK CONFIGURATION

255

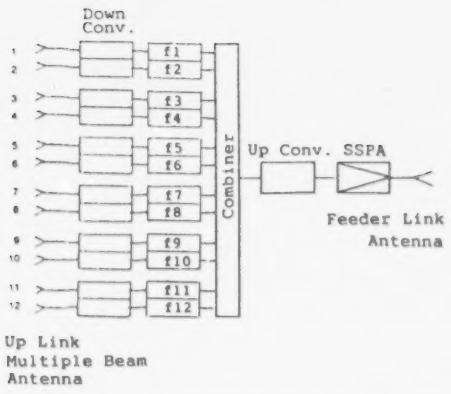

FIG. 6 SATELLITE IN BOUND LINK CONFIGURATION

6. STUDY ON EARTH STATIONS

6.1 MOBILE STATION

A mobile station is to be installed on an automobile, a train or a small ship. To increase the transponder capacity, a satellite tracking directional antenna is used. To decrease out door profile, a flat dic antenna shown in Fig. 7 is selected.

A block diagram of the mobile station is shown in Fig. 8 and major parameters in Table 2.

Table 2. Major parameters of mobile station

Frequency	: S band
Antenna	: steerable phased array, 0.5m diameter, gain 13 dB
Transmitter	: 5W SSPA
G/T	: -11 dB/K
EIRP	: 20 dBW

6.2 TRANSPORTABLE STATION

A temporaly and emergency use transportable earth station is similar with the mobile station except the antenna which is a fixed directional one. The major parameters are shown in Table 3.

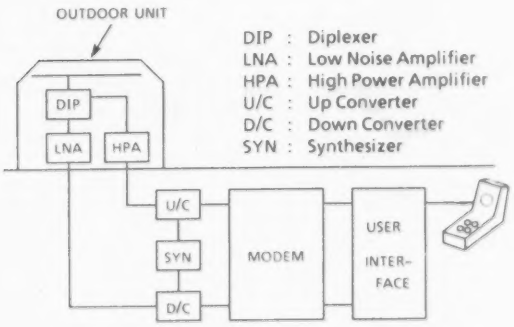

FIG. 8 BLOCK DIAGRAM OF MOBILE STATION

Table 3 Major parameters of transportable station

Frequency	: S band
Antenna	: meshed parabolic dish of 0.8m diameter (gain = 23 dB)
Transmitter	: 5W SSPA
EIRP	: 30 dBW
G/T	: -2 dB/K

6.3 BASE STATION

It is a popular earth station for fixed satellite communications.

Channel assignment functions using common signaling channels are required. Major parameters of a base station is shown in Table 4 in case of 250 channel capacity.

Table 4 Major parameters of base station

Frequency	: C band
Antenna	: parabolic dish of 5m diameter (gain = 48 dB)
Transmitter	: 20W SSPA
EIRP	: 61 dBW
G/T	: 24 dB/K
Capacity	: 250 channels

6.4 LINK BUDGET

An approximate link budget of the mobile link is given in Table 5. The feeder link budget is omitted because it is not critical.

Table 5 Link Budget of mobile link

item	mobile	transportable
SATELLITE		
EIRP (dBW)	53	53
BACK OFF (dB)	2	2
PATH LOSS (dB)	191.9	191.9
MOBILE/TRANSPORTABLE		
G/T (dB/K)	-11	-2
DOWN LINK C/No (dBHz)	76.7	85.7
MARGIN (dB)	2	2
REQ'D C/No (dBHz)	full: 46.8 half: 44.4	full: 46.8 half: 44.4
TPDR CAPACITY (ch)	full: 980 half: 1700	full: 7760* half:13490*
MOBILE/TRANSPORTABLE		
TX. POWER (dBW)	7	7
ANT. GAIN (dB)	13	23
EIRP (dBW)	20	30
PATH LOSS (dB)	192.2	192.2
SATELLITE		
G/T (dB/K)	5	5
UP LINK C/No (dBHz)	61.4	71.4
MARGIN (dB)	2	2
REQ'D C/No (dBHz)	full: 46.8 half: 44.4	full: 46.8 half: 44.4

* Derived from power limit. Frequency limit should be considered.

With regard to the full rate codec, the capacity of the down link is about 1000 channels and it is 2500 channels with VA.

In case of the half rate codec, the capacity is 4000 channels with VA.

7. ECONOMIC FEASIBILITY

The mobile station cost and the transponder leasing cost are evaluated.

The mobile station cost is estimated around 3--4 K US dollars in the mass production phase. Assuming 4 K dollars, it may be recovered by a 500 dollars initial payment and a 80 dollars monthly rate.

Though the S band transponder rate is unknown, let us assume it is equal to five Ku band transponders. Including a C band feeder link transponder, total of 20 M US dollars per year is assumed.

Above costs do not include costs of base stations, communication controls, general and administration expenses. These costs depend on number of base stations and the way of business operations, etc, and probably less than the transponder rate.

Besides of these, the ground link cost should be taken into account.

The transponder rate will be recovered by the following communication fee charged on the traffic.

The traffic is assumed as follows.

(1) The busy hour traffic is 50 percents of the total capacity.
The traffic will grow from initial small quantity to some amount later and the average is assumed 50 percents.

(2) The traffic in a day is ten times of the busy hour traffic.

In the case of the full rate codec, the fee per minute is calculated as

$$\frac{\text{transponder}}{20 \times 10^6} \Big/ \frac{\text{days} \times \text{hours} \times \text{minutes} \times \text{capacity} \times \text{load}}{365 \times 10 \times 60 \times 2500 \times 0.5}$$

= 7.3 US cents / minute

This is the fractional fee corresponding to the transponder rate only.

Similarly, the fractional fee for the half rate codec is calculated as 4.6 US cents/minute.

8. CONCLUSION

Using the codecs for digital mobile telephone systems, mobile satellite communication systems will be realized economically. A satellite having a multiport amplifier can cover wide areas as Asia and Pacific.

I appreciate Messrs. Kunio NAKAJIMA and Shinya TAKAHASHI (Mitsubishi Electric Corp.) helping us about codecs.

ABSTRACT

Single channel per carrier (SCPC) and demand assigned, multiple access (DAMA) techniques used in thin route satellite communications provide an attractive method of reducing space and ground segment costs. Instead of dedicated point-to-point links, the system assigns the satellite resource on demand. A much smaller amount of satellite bandwidth can be shared, thus taking advantage of the random and occasional nature of telephone traffic. Since a DAMA system assigns bandwidth on a per call basis, full mesh single hop connectivity is possible—a significant added benefit. This paper examines various architecture alternatives to mesh DAMA SCPC systems and Scientific-Atlanta's approach.

Single channel per carrier (SCPC) systems can be used for satellite based telephony applications where terrestrial solutions are impractical or prohibitively expensive. These thin to medium route systems are economical, reliable and can be deployed quickly. Satellite links are pre-assigned based upon traffic needs at installation time. The pre-assigning of links and the simultaneous multiple access by several sites results in the term PAMA—pre-assigned multiple access.

Each SCPC voice channel is modulated directly on a separate pre-assigned RF carrier, offset from other carriers, on a frequency array that spans the assigned satellite transponder bandwidth. A given telephone call between two sites uses two fixed carriers—one transmitted from each site. Typical frequency spacing is 30 kHz, thereby allowing many carriers in a single transponder. All carriers transmitted from a single site are combined at an intermediate frequency (e.g., 70 or 140 MHz), up-converted to the C- or K_u-band satellite frequency, and transmitted to the satellite.

The received signal is down-converted back to the intermediate frequency (IF) and passed to channel equipment that demodulates the individual carriers. The result is a toll quality link with a small (i.e., roughly 1/4 second node-to-node) delay.

Communication capacity is allocated on a channel-by-channel, site-by-site basis. Thus, in PAMA systems site-to-site connectivity is determined at installation time. New channels can be added one at a time as the system grows by adding an additional channel unit at each site. As traffic patterns shift, capacity can be rerouted by moving channel units and frequency assignments from one site to another.

THE CASE FOR DAMA

Demand assigned multiple access (DAMA) is the next logical development step for SCPC systems. It provides a powerful means for extending the capacity of these systems. Under DAMA control, the SCPC channel connections between stations are dynamically assigned to fit the immediate demands of the traffic load. Because the satellite resource can be shared by all stations, the traffic engineers can size the bandwidth to match overall traffic needs.

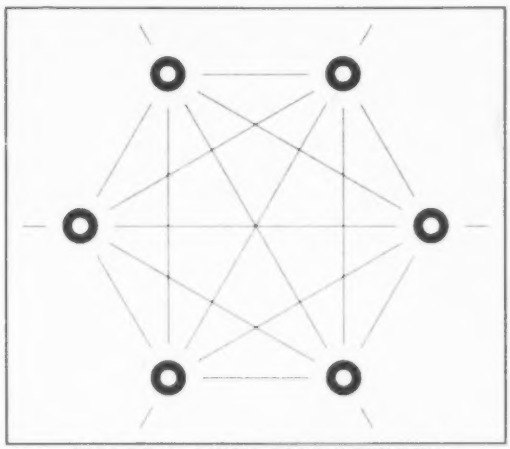

FIGURE 1—MESH CONNECTIVITY

With DAMA, connectivity is dramatically improved. Instead of pre-assigning satellite links, the DAMA system assigns the links as connections are needed, thus exploiting the satellite's ability to connect distant sites to one another.

Connectivity can be achieved in one of two ways. Star connectivity occurs when connections are switched at a master site. Each link in a star configuration requires two hops over the satellite (except for calls that terminate at the master site). Channel equipment at the master site is required for the maximum number of links in the system.

Full mesh connectivity, on the other hand, allows single hop site-to-site connectivity. (Star and mesh connectivity are discussed in more detail below.) Figure 1 is a diagram showing six nodes and all possible connections between them. The number of possible connections is represented by the following formula:

$$L = \frac{(N \times (N-1)) \times C}{2}$$

where:
- L is the number of bi-directional links
- N is the number of nodes
- C is the number of circuits between nodes

If each of the six nodes in Figure 1 are to be connected to the remaining five nodes with one circuit, fifteen bi-directional links are required. While this results in full connectivity, only one circuit is available between a given pair of nodes. Therefore, a second connection cannot be made, even for a short time. Each node would need five channels, even if a given node never had more than one call at a time.

Full mesh connectivity done with dedicated point-to-point connections becomes unworkable for large systems. A 100 node system, for example, requires 4,950 bi-directional links. A system thus connected would require 99 channel cards (N-1) at a small site having full connectivity, and therefore 9,900 channel cards for the entire network—clearly an economically infeasible approach. The same network with full mesh DAMA connectivity would require 100 channel cards and only one bi-directional link for a given phone call. Therefore, a demand-based sharing of the satellite link not only saves space segment resources, but also ground equipment.

APPLICATIONS

A number of technologies have matured in recent years to make a full mesh satellite-based SCPC/DAMA system practical. These technologies include satellite modems, computer hardware, digital signal processing (DSP), voice compression software, solid state power amplifiers, and communication satellites. The near universal acceptance of digital telephony has also helped reduce the barriers to such systems. These technologies have reduced the size, power consumption, development effort, and cost while at the same time increasing system reliability.

The resulting dramatic reduction in procurement and operating cost makes SCPC systems more practical and financially attractive. The primary application of SCPC DAMA systems is rural telephony—to bring telephone service to people who do not have it. Several other applications for satellite-based telephony are also covered by such a system, namely:

1. Thin route telephony, new service
2. Thin route telephony, additional trunking
3. Private or VIP networks
4. Emergency or backup networks
5. Rapid deployment telephone service for new markets or disaster recovery

In addition to the above, there is a growing demand for the retrofit or expansion of existing satellite-based analog SCPC systems.

TRAFFIC CONSIDERATIONS

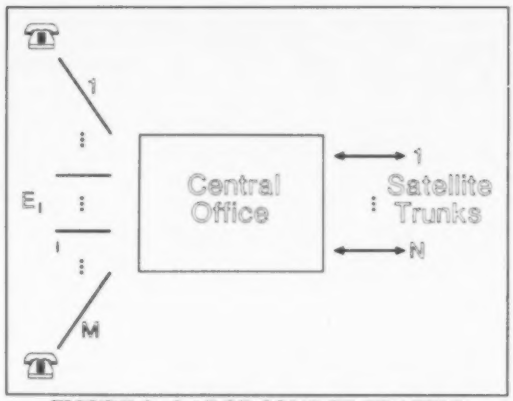

FIGURE 2—LARGE SOURCE TRAFFIC

Traffic accessing the satellite network can be characterized as large source and small source. Figure 2 shows the large source case. The traffic generated from telephones shown at the left of the diagram is concentrated by the central office or PABX and presented to the satellite system as trunks 1 through N. Typically the number of trunks presented to the satellite network would be six or more but fewer than 100. The traffic presented to the satellite system is predicted by the following formula:

$$E_T = \sum_{i=1}^{M} E_i = \eta_T \times N$$

where:
- E_T is the total traffic presented to the system in Erlangs
- M is the number of telephone lines
- E_i is the Erlang loading of each telephone
- η_T is the trunk efficiency
- N is the number of trunks

The trunk efficiency (η_T) is a measure of the loading per trunk and is a function of the number of telephones (M), the number of trunks (N), the Erlang loading per phone (E), and the desired grade of service or probability of blockage (P). The following table shows trunk efficiencies for three different cases. It is assumed for this example that the Erlang loading per phone is 0.1 (E_i = 0.1) and a desired probability of blockage is 0.02 (P = 0.02).

253

Trunk Efficiency		
M = 20	M = 50	M = 500
E_T = 2.0	E_T = 5.0	E_T = 50.0
N = 6	N = 10	N = 60
g = 33%	g = 50%	g = 83%
E_N = 0.33	E_N = 0.5	E_N = 0.83

Figure 3 is a diagram of typical small source traffic loading. The figure shows a PABX which switches local calls and hands other calls over to the satellite based system for connection. The second case shows unswitched connections where each phone is connected directly to a channel unit and is always switched over the satellite. Typical values for E_N and N are 0.2 and 4, respectively.

Typically small to medium thin route systems have low trunk efficiencies. These systems, whether switched or unswitched, receive the greatest benefit from DAMA. Although the trunk efficiencies are low, the satellite circuit utilization can, by the use of DAMA, be increased to near 100 per cent provided that the channel pool is sufficiently large.

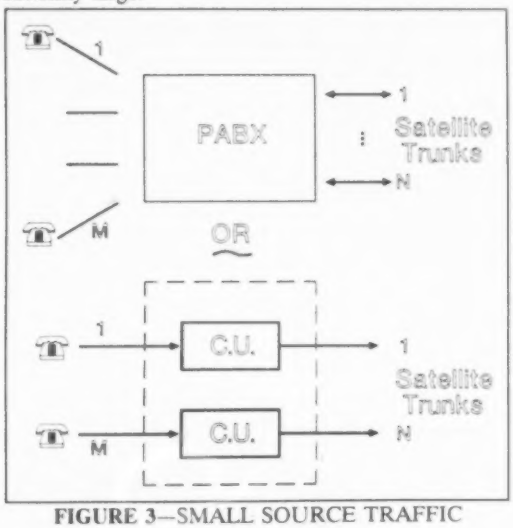

FIGURE 3—SMALL SOURCE TRAFFIC

STAR DAMA

In a star DAMA network (depicted in Figure 4), all traffic is routed through the master site for connection. The master site must coordinate the sharing of the satellite resource. This is accomplished via a common signalling channel that has an out-link from the master and a return-link shared by each remote. Status, requests for service, and frequency assignments are all made using the common signalling channel.

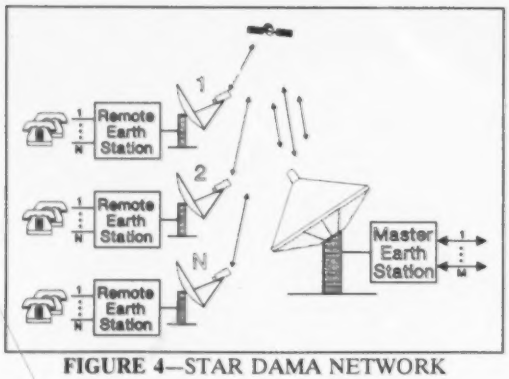

FIGURE 4—STAR DAMA NETWORK

A call from a remote site terminating via a terrestrial interface at the master site would use two frequency assignments. The remote site would transmit on frequency F1 and receive frequency F2. The master would receive F1 and transmit F2. One channel unit at the master and one at the remote would be needed for the duration of the call.

Intra-system calls (i.e., calls that originate and terminate within the satellite system) are switched at the master and connected using a second satellite link. In an intra-system call, two frequency pairs are used. The first remote site transmits on F1 and receives on F2. The second remote site transmits on F3 and receives on F4. The master receives F1, switches it to F3, and transmits F3. The master also receives F4, switches it to F2, and transmits it. The resulting double hop arrangement has twice the satellite delay and uses twice the space segment power and bandwidth. The call requires one channel unit at each of the remote sites and two channel units at the master for the duration of the call.

By assigning frequency pairs only when needed, a substantial reduction in the total bandwidth can be achieved. The resulting bandwidth savings or capacity efficiency is called DAMA gain. Using the Erlang "B" model, DAMA gain for a star mesh system can be computed using the following formula:

$$G_D = \frac{C \times N}{N_S}$$

where:
- C is the number of channels per remote site
- N is the number of remote sites
- N_S is the number of satellite trunks required for a specific grade of service P

Typical values for DAMA gain range between 3.0 and 5.0. The higher the allowable probability of a blocked call, the higher the DAMA gain. Even with an allowance for double-hopped calls, overall efficiency is improved.

A star DAMA configuration has two other signifi-

cant advantages. Because all calls are routed through a central site, a conventional switch can be used to connect calls. Another advantage is that relatively smaller antennas can be used at the remotes since direct remote-to-remote links are never made. Each remote site needs only enough channel cards to support the traffic to and from that site and the master station needs only enough channels to support the total traffic load of the network, but reduced by the DAMA gain.

FULL MESH DAMA

A full mesh DAMA network (depicted in Figure 5) requires single hop site-to-site connectivity. An intra-system call results in a bi-directional channel directly from one remote site to another. One remote transmits a carrier at frequency F1 and receives a carrier on frequency F2. The other remote transmits on F2 and receives on F1. The master site is not needed to relay the call.

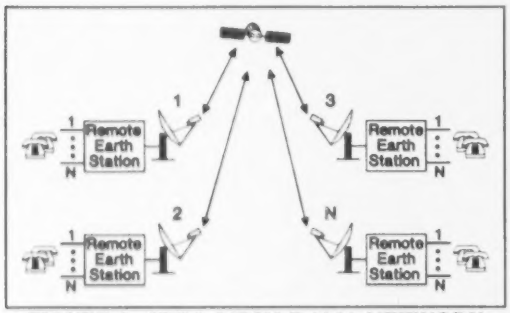

FIGURE 5—FULL MESH DAMA NETWORK

This arrangement uses half the space segment of a star DAMA system for an intra-system call, but it requires more sophistication in the overall architecture. A signalling channel is required to allow sharing of the space segment resource as with the star DAMA system. Since any remote site can be connected to any other remote site, and because remotes typically have varying antenna sizes, uplink power control is required. Each transmitted carrier must be adjusted in power to match that required by the differing uplink and downlink dish sizes.

Another challenge for DAMA systems results from the inherent high connectivity. Instead of routing calls through a central switch which has pre-defined circuit types for various equipment, the mesh network must accommodate the connection of varying types of circuits.

The DAMA gain in this case can be expressed by the following formula:

$$G_D = 0.5 \times \frac{C \times N}{N_S}$$

where **C**, **N**, and N_s are the same as above.

SCIENTIFIC-ATLANTA'S APPROACH

Scientific-Atlanta's Skylinx.DDS Digital DAMA System is designed for thin to medium route telephony applications where full mesh point-to-point connectivity is important. The system makes maximum use of digital signal processing (DSP) and modern electronic packaging techniques. The system was designed for economy of purchase, high reliability, and low maintenance. Telephone, voice band data, and facsimile traffic are carried from one site to another using a single satellite hop. The routing between various sites can be pre-assigned multiple access or demand assigned multiple access. Pre-assigned links and demand assigned links can be mixed within the system.

Figure 6 is a system block diagram of S-A's Skylinx.DDS system. Shown in the diagram is the master station site which is responsible for central control of the system. Three remote sites are also depicted. Two types of channel cards are shown in the diagram. The voice channel unit (VCU) is used to digitize and modulate/demodulate telephone, data, or facsimile traffic. The signal channel unit (SCU) is responsible for system signalling and remote site control. Using separate signalling hardware facilitates maintenance functions (e.g., rapid detection of failed channel hardware) and allows custom calling features (e.g., call waiting).

To conserve satellite power, each carrier is voice activated. During periods of silence, the carrier is dropped, thus saving up to 4 dB of the satellite power. Rapid re-acquisition and data buffering result in an unclipped and apparently seamless telephone connection. Transponder power and bandwidth can be saved while still offering a high level of service.

To guarantee an even higher level of service to critical circuits, the DAMA Controller allows each circuit to be assigned a priority level. Bandwidth can be subdivided so high priority calls get through regardless of the load placed on the system.

Each system has at least one master site and any number of remote sites. Redundancy at the master site protects portions of the system that effect more than one telephone circuit. Redundancy is available at each remote site, as an option. Because of its intended use in rural areas, the system equipment is designed for unattended operation. System monitoring, maintenance testing, data base changes, and traffic data collection can all be performed from a location remote from the equipment.

The system uses advanced voice compression technology. This technology, when coupled to the system's single card modem, provides high quality digital voice using less bandwidth than analog solutions.

A comprehensive software package allows the operator full flexibility to grow and change the system. This package combines call processing, maintenance, and administration software with system-wide monitoring and

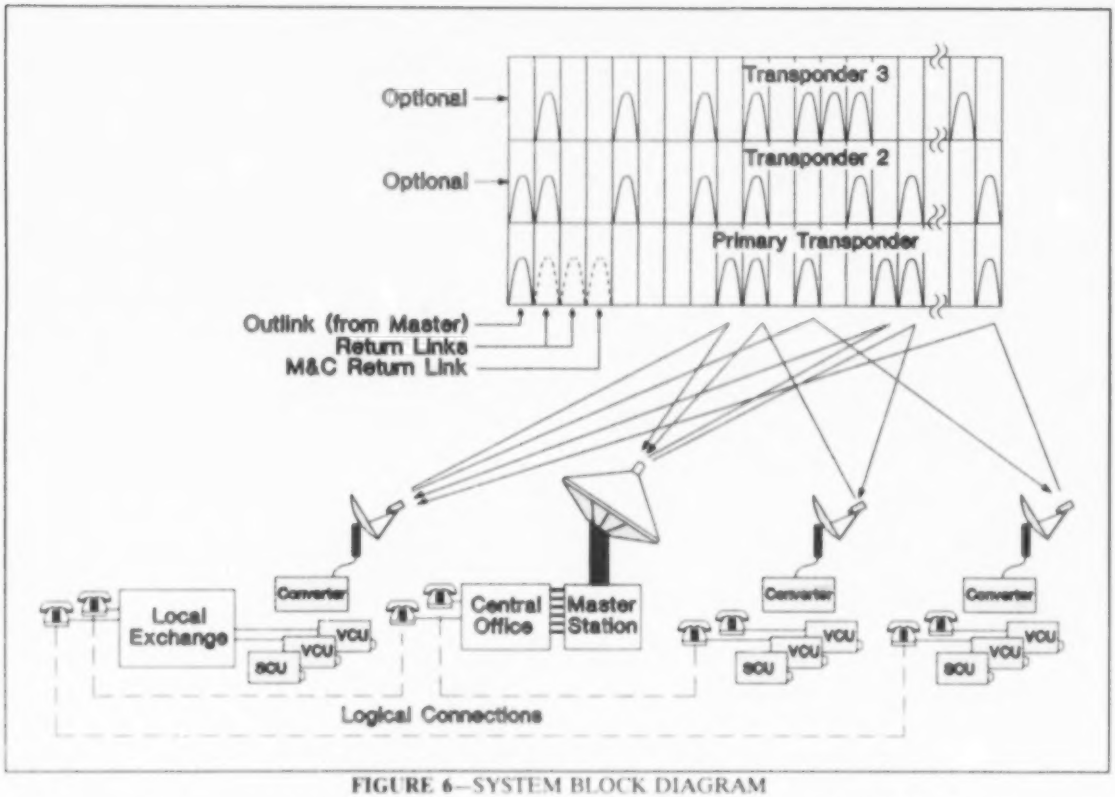

FIGURE 6—SYSTEM BLOCK DIAGRAM

control software. The operator thus keeps in touch with the entire network from a single location.

The system uses a common signalling channel to communicate with the remote sites. This signalling channel consists of a continuous outbound link that is received by each remote and one or more return links as shown in Figure 6. Each remote responds on a return link in burst mode using slotted Aloha. Slotted Aloha is a technique that allows each remote site to send an unsolicited message when it needs to so long as the message begins and ends within a predefined slot time. It represents an excellent compromise between channel throughput and rapid response time.

A separate monitoring and control (M&C) return link uses polling to ensure that service effecting failures are quickly detected.

Modem Technology

The satellite modem employed is a low bit rate SCPC digital signal processing (DSP) based design. This modem operates at two synchronous data rates which are 32 kb/s, 16/2 kb/s, 16 kb/s, 8/4 kb/s and 8 kb/s. The modulation scheme is QPSK at 32 kb/s and QPSK or BPSK at the lower rates. Forward error correction using convolutional coding and Viterbi decoding improves channel performance and acquisition time. Available code rates are 1/2 and 3/4. After initial call setup, the modem acquires carrier quickly (less than 30 ms) to permit voice activation.

This modem plays two roles in the system:

- One is to transport compressed digitized voice or user data over the satellite channel with an acceptable error rate in worst case conditions as part of the VCU.
- The other is to transport the signalling information for each site as part of the SCU.

The modem is a single card design that plugs into the backplane of the chassis. From this backplane, it receives power and communication access to the primary SCU and standby SCU (if equipped). The voice compression CODEC/terrestrial interface is a separate module that is plugged into the modem card. The modem is an all digital design except for the analog 70 MHz upconverter/downconverter and synthesizer. The board incorporates surface acoustical wave (SAW) filters and surface mount technology.

The carrier recovery loop in the SCU modem monitors the frequency of the master station out-link. The continuous out-link from the master can then be used as a system pilot. This eliminates the need for separate dedicated pilot receivers that were used in earlier analog systems.

Common Signalling Channels

Each system has one signalling channel outbound from the master station and one or more return signalling channels. The master station computer operates the entire network using these channels. The signalling channels carry various messages needed to establish, maintain, and terminate network telephone and data connections. System-wide monitoring and control information is carried over a separate return link.

Each signalling channel is operated by an SCU at the master station. These master SCUs are referred to as MSCUs. Each remote site may be equipped with a single SCU or a redundant pair. These remote SCUs are referred to as RSCUs and are identical to MSCUs except for the firmware. The master site communicates with the remotes via a continuous outbound link. The outbound signalling carrier protocol is HDLC. If the master has no messages to send, it sends flags. Each remote SCU continuously monitors this stream of data for messages addressed to its site ID. When it decodes a message for its site, it responds as appropriate on its designated return channel. Remote sites send responses and requests for service via one or more slotted Aloha return links.

The first MSCU is used to generate the continuous out-link. The receive portion of the first MSCU is used to monitor the out-link signal from the satellite so that a failure of the signalling channel is immediately detected. The DAMA controller will immediately begin using the backup MSCU if a failure occurs.

Transponder Utilization

The Skylinx.DDS channel card is frequency agile so that any bandwidth within a given transponder can be used for a given phone call. For large systems a second or even a third transponder can be used. Converter equipment is required to perform the conversion from the system IF to the final transponder frequency. All sites in the system must have equipment to transmit and receive on the primary transponder (transponder 1). The primary transponder is used for the system signalling channels and telephone traffic. To reduce cost, small sites need have no additional converter equipment, so calls to and from small sites will always be assigned to the primary transponder.

Medium sized sites have two converters (and typically, a standby) to transmit and receive from transponders 1 and 2. The master station computers can connect a call using either transponder based on loading, with a default of transponder 2. Large sites may have three converters (and a standby) to transmit and receive from any of the three transponders. The master station computers can connect a large site to a large site on any of the three transponders with a default of transponder 3. By using the highest possible transponder to connect a call, the system preserves the lower number transponders for calls to/from the smaller sites. In order to have full site to site connectivity, every site must be capable of communicating on the first transponder.

The system allocates satellite bandwidth from groups. Group types are signalling, call, and services. The call group is further subdivided into priority. Bandwidth is assigned for each call according the originating circuit priority. The call is assigned bandwidth from the lowest priority group. If there is no low priority space remaining, it is assigned space from the medium priority bandwidth if its priority is medium or higher. If no medium priority space is available, it is assigned high priority space if it is a high priority circuit. If no space is available, the call processing software gives the caller a re-order tone and appropriate blocked-call counters are incremented. Bandwidth may span more than one transponder, up to a maximum of three transponders.

Uplink Power Control

Each VCU has three power levels—low, medium, and high. During call setup, the master station determines the caller and called site characteristics and commands each VCU to go to a power level that is appropriate for the call. The power level used at each site takes into consideration the site's uplink performance and the receiving sites downlink performance. The difference between the high and low power setting is approximately 12 dB.

SUMMARY

The three critical considerations in any satellite based telephone system are voice quality, system availability, and cost. Each of these considerations has an initial and recurring component. Voice quality must be high initially and reasonably immune to noise and long term changes in the system. The system must be reliable when it is commissioned and continue operating when inevitable equipment failures occur. Finally, the per channel and overall system cost must be kept as low as possible, the space segment must be utilized efficiently, and the long term maintenance costs must be minimized.

Digital transmission paired with speech coding offers an alternative to traditional analog transmission techniques. Digital Signal Processing (DSP) and voice compression technology have made it practical and cost effective to use digital transmission techniques. The analog voice signal can be digitized, compressed, and sent over the satellite. Reversing the operation, the destination site reconstructs the original analog waveform with little or no noticeable degradation. When used in lieu of analog methods, digital transmission improves the quality and reliability of the link.

DAMA systems require computers to perform control of the system and allocation of the satellite resource. Modern technology has made computers and the software that runs them more affordable. Therefore the overall system becomes more commercially attractive and easier to justify from an economic standpoint. The combined effect of the converging technologies used in DAMA systems and modern satellites results in a system that can provide high quality service and have a reasonable return on investment.

The Impact of Competition in Satellite Launchers and Spaceports on Pacific Telecommunications

Arthur L. Levine
Professor, Department of Public Administration
Baruch College, City University of New York
New York, New York, USA

1. ABSTRACT

Lower cost, lower risk launches of communications satellites may be expected as a result of increasing competition in launch services, the growing number of commercial spaceports, and other factors. These developments could enhance the feasibility of providing improved Pacific telecommunications.

2. INTRODUCTION

Substantial reductions in the cost and risk of launching communications satellites may be expected by the end of this decade. This prospect is due to fierce competition in launch services, the growing number of spaceports available for commercial launches, and improvements in the technology and reliability of launch vehicles. Lower costs and risks should occur simultaneously with the advent of new satellite communications systems, particularly for mobile services, and increased capabilities of satellites and ground equipment.

The confluence of these developments could bring enhanced telecommunications to nations in the Pacific region and could be a boon to providing sorely needed telephone and other communications services to developing countries. These outcomes may not be realized, especially for developing countries, unless other factors become more favorable to greater accessibility to satellite communications services. These are: frequency allocations for the mobile satellite service (MSS), competition in satellite communications and associated telecommunications services, network access, and regulation.

3. LAUNCH VEHICLES AND SERVICES

Competition among launch vehicles, capable of boosting medium to heavy payloads, is fierce (Table 1). The market for commercial launches by this class of vehicles is limited: only 15 to 20 launches per year for the next eight years.(3, 5) Launch firms have engaged in strong price competition which may become more intense as new or upgraded launchers come on line. Launch firms aim to capture business from military and civil government projects, but with shrinking budgets, prospects for a large market in such launches are in doubt. It is likely, therefore, that communications satellites will continue to account for a significant share of the commercial launch business, adding to competitive pressures.

Lightsats (weighing up to 2000 lbs.) may be launched to low Earth orbit (LEO) or to geostationary transfer orbit (GTO) as part of a multiple payload on large launch vehicles or to LEO by small launch vehicles. Price competition among small vehicles and with their larger counterparts will also be vigorous.

In addition to providing the launch vehicle, launch firms also offer a package of services which include payload processing, direction of launch operations, insurance or insurance options. For example, McDonnell Douglas offers add-on options for contracts for its Delta launch vehicles, including limited insurance to satellite owners: the choice of a free launch or a refund if a satellite failure is due to some fault of the rocket. Price competition for such associated services either offered as a package or as options is also expected to accelerate as new launch vehicles and firms enter the market.

4. SPACEPORTS

Competition among spaceports offering commercial launches will be heating up in the next few years. In addition to the spaceports currently operating, more are planned or under study. (Table 2). There is sufficient capacity to accommodate all current commercial launches of large, medium, and small satellites in two existing launch sites--the Ariane launch base near Kourou, French Guiana, (which handles nearly half of all such launches) and Cape Canaveral, Florida, U.S.A. Other spaceports account for a lesser share of launches due to

TABLE 1

Competition Among Large Commercial Launch Vehicles

Launch Vehicle	PAYLOAD CAPACITY LEO	GTO
Ariane 4 (ESA-Arianespace)	21,000 lbs.	9,200 lbs.
Atlas 2 (U.S.A-General Dynamics)	14,500 lbs.	5,900 lbs.
Atlas 2AS (U.S.A.-General Dynamics)	18,500 lbs.	7,700 lbs.
Delta 2 (U.S.A.-McDonnell Douglas)	11,100 lbs.	4,010 lbs.
Long March CZ-3 (PRC-Great Wall Industry Corporation)	7,250 lbs.	3,100 lbs.
Titan 3 (U.S.A.-Martin-Marietta)	32,000 lbs.	10,500 lbs.
Zenit SL-16 (USSR-Russian & Ukraine Republics)	33,000 lbs.	9,900 lbs.
Under Development		
Ariane 5 (1995: ESA-Arianespace)	44,000 lbs.	15,000 lbs.
H-2 (1993: Japan-Rocket Systems Corporation)	22,040 lbs.	8,810 lbs.
Long March CZ-2E (1992: PRC-Great Wall Industry Corporation)	19,400 lbs.	6,500 lbs.
Under Study		
National Launch System Commercial Derivative (2005: U.S.A. -Government R&D)	20,000 lbs.	NOT DETERMINED
Proposed by COMSTAC Innovation & Technology Group		
Low-cost ELV (1999: U.S.A. -Government R&D)	20,000 to 40,000 lbs.	9,000 to 15,000 lbs.

JAPAN	Tanegashima
PEOPLES REPUBLIC OF CHINA	Xichang, Sichaun Province Jiuquan, west of Beijing Taiyuan, Shanxi Province
SOVIET UNION (REPUBLICS OF)	Baikonur (Tyuratam) Plesetsk
UNITED STATES	Cape Canaveral, Florida Hawaii (two sites under study) Point Plata, Alaska (under study)

limited commercial space activity in their countries or other factors. In the case of the Tanegashima launch site in Japan, launches are limited to two periods a year due to objections from fishermen who fear that shuttle will spoil their catches.

Planned or proposed spaceports include launching sites to be operated by the states of the U.S.A. The Florida Spaceport Authority is planning an early 1991 sounding rocket launch from Cape San Blas, Florida. The authority also has a long range plan to refurbish a U.S. Air Force launch pad at Cape Canaveral to accommodate small satellite launches, providing market prospects are favorable. The state of Hawaii is pushing to build a spaceport for small and medium satellite launches on one of two sites on the Big Island of Hawaii. Financing is being sought from private sources. An environmental impact study is underway. Environmentalists and local residents near the prospective sites are opposing the spaceport initiative. Private firms have expressed interest in launching small satellites from a sounding rocket firing range owned and operated by the University of Alaska at Poker Flats, Alaska. Facilities may be upgraded for launching of small satellites should a market feasibility study prove favorable.

The Air Force Phillips Laboratory Systems Directorate at Kirtland Air Force Base has issued a request for proposals for a spaceport at Cape Cod in southeast Massachusetts. Launches of the launch vehicles may be made from this site. This was first begun to get backing from industries in Japan, Europe and the United States. Earlier efforts to locate a spaceport from Massachusetts sources have encountered opposition. The environmental impact study has not begun. The proposed launch operations site

a variety of launch vehicles of the three major U.S. launch firms--General Dynamics, Martin Marietta, and McDonnell Douglas. Proximity to the North Pole of the Kodiak Flats site is an advantage for launching into polar orbits.

[illegible]

The sites will use many new LEO systems for satellite communications including those designed for worldwide mobile telephone service. New small vehicles for launching lightsats into LEO are hoped to attract new launch users. Among such vehicles are the Pegasus, which is launched from an airplane in flight, developed by Orbital Sciences Corp. and the Orbital Express under development by Interorbital Systems. Although the LEO satellites would go on large vehicles as part of multiple payloads with others launch users.

[illegible]

Advances in miniaturization of satellite electronics and other technologies is a major factor in accounting for the growing interest in orbiting small satellites. Technological gains were also helping to make launch vehicles and spaceport operations more efficient. Large launch vehicles under development will have increased capacity to handle up various combinations of payloads. The volume of small satellites weighing a fifth of a ton, the lower end of [illegible] vehicles would have to aggregate launches of several satellites to make the launch cost effective. Small launch vehicles under development will have the capacity to launch satellites weighing a fifth of a ton. The lower end of [illegible] vehicles would have to aggregate launches of several satellites to make the launch cost effective. Small launch vehicles under development will have the capacity to launch satellites weighing a fifth of a ton. The lower end of [illegible] vehicles would have to aggregate launches of several satellites to make the launch cost effective.

the interactions on mission configuration and sparing/maintenance strategies."[9]

The financial simulation model developed by Greenberg and Christensen demonstrates that while high launch cost may be offset by other factors, there also may be a situation in which low reliability and high insurance rate are more than compensated by lower launch cost and higher payload placement accuracy.

Lower launch costs, especially when combined with lower risk, could enhance the feasibility of satellite communications ventures. Launch costs are among the significant up-front expenditures for which financing is more difficult as costs escalate. Motorola is interested in obtaining free launch contracts in exchange for stock in its new Iridium mobile satellite project. Motorola estimates that it will cost at least $570 million for launches of its initial constellation of 77 small LEO satellites according to its filing with the U.S. Federal Communications Commission. Additional funds will be needed to send up replacements. The Soviet Union has expressed investment interest by providing free launch services since they do not have hard currency to offer. The prospect for lower risk launches is one factor which has encouraged new ventures. The decision by Motorola to move ahead with Iridium was influenced positively by this prospect, as well by availability of technologically advanced lightsats.[1]

7.2 COMPETITION

Competition in international satellite communications is emerging. Steps are being taken to ease entry of competitors to Intelsat and Inmarsat. PanAmSat has moved ahead with plans to launch a hybrid C/Ku-band satellite in the mid-1990s for Pacific Ocean region services. Columbia Communications, despite financial problems, is pursuing its plans to lease C-band transponders on a NASA tracking and data satellite in orbit above the Pacific Ocean. Operation of these new systems, combined with existing and planned regional satellite systems serving the Pacific, will expand considerably the options available to users. Growing fiber optic capacity is an additional competitive factor that adds options. Satellite services, however, will remain in demand especially for rural and remote areas, and wherever their use in combination with terrestrial services is more economical or efficient. One benefit of new satellite system entry is that it will provide for higher power satellites, enabling users to receive on smaller antennas with potentially more economical ground equipment and opportunity for further VSAT usage.

7.3 NETWORK ACCESS

Restrictions to network access for satellite and associated services may hurt their accessibility and affordability. As Hudson notes, despite the availability of VSATs and other relatively low cost technologies (VHF, UHF, rural subscriber services, microwave systems, cellular radio, etc.), large parts of the population have no access to reliable communications. While some technologies, such as a microcomputer, can be used "stand alone," a telephone set or a VSAT are useless by themselves. They require a network. In many developing countries, access to networks are hampered by legal restrictions or PTT controls. Although such barriers are receding in many countries, their persistence in some nations will hamper realization of affordable services especially for rural and remote users. Hudson describes a number of strategies for overcoming obstacles ranging from the introduction of autonomous public ownership, a mixed public/private corporation, and privatization. She also notes that satellite communications could play a special role in promoting competition for long distance telephony within a developing country. "Long distance competition in the public network is probably not justified in most developing countries at present because of the dangers of wasting scarce resources on redundant capacity and difficulties in interfacing with local networks. Countries with domestic satellites can introduce long distance competition by allowing the satellites to be used even when terrestrial capacity exists. This approach in India and Indonesia, for example, would enable subscribers to bypass the bottlenecks in major cities."(12)

7.4 REGULATION

To promote widespread, affordable use of satellite communications, regulatory approaches, both international and domestic, must take into consideration the impact of frequency allocation and of standards and prices on the quality and accessibility of satellite services. In cases where an autonomous government structure is set up, oversight is needed to insure that a single provider does not abuse monopoly power in setting rates or discriminating between customers. In a competitive environment, less regulation will be needed, but where demand far exceeds supply, prices may be so high that services for rural and remote users become out of reach. In such cases, explicit subsidies may be warranted. (Subsides should be explicit to prevent a dominant carrier from engaging in predatory pricing.) In the quest for bringing low cost services to rural and remote areas, caution must be exercised by regulators to make sure that prices are not set too low. Government pressure to keep rates down may leave a carrier without adequate resources or facilities.(12)

8. CONCLUSION

The goal of providing enhanced Pacific telecommunications could be furthered by the growing competition among launch services and spaceports. It is important, however, to recognize that launches are only one element in a complex web of factors which influence cost and accessibility, especially for developing countries. Steps must be taken to insure that competition also extends to other aspects of satellite communications and that international and national oversight of telecommunications is geared to facilitating the affordability and accessibility of emerging satellite communications services.

Sally Yeates Sedelow, Professor
Computer Science Department,
University of Arkansas(UA)/Little Rock;
Adjunct Professor, Electronics and Instrumentation, UA/Graduate Institute of Technology

ABSTRACT

We have developed a computer-based methodology for representing intellectually substantive interdependencies among components (e.g., courses, programs, departments, curricula; faculty members) within and among universities. Extended Petri Nets provide the formal basis for this technology. Among the applications in the Pacific region for these education-modelling techniques is the coordination into coherent (and degree-qualifying) programs of study of individual courses taken at a number of institutions, even in different countries and cultures with diverse degree requirements.

The research and development efforts being reported on in this paper, while free-standing and independently employable, are part of a larger research enterprise. That larger research undertaking we have designated Symbol Systems Access--SSA, pronounced 'Say'. The phrase Symbol Systems Access is meant to establish a rubric under which we may properly encompass not only natural languages, taken as systems of symbols (whether in 'written' or oral form), but also all other 'languages,' in the most extended definition of that term--so as to include mathematical, logical, iconographic, musical, and any other (Rough (3)) sets of symbols which in use manifest combinatoric linearities.

The motivation for studying aspects of Symbol Systems Access is an effort aimed ultimately at improving, hopefully radically or even by some criteria optimizing, the availability of such systems for use by our species (9). One underlying and Enlightenment assumption is that through access to symbolic 'capital,' as stored in texts and the like, on average people do better in relating to their environments, not least of all for being able to work through the implications of possible actions symbolically (as in 'gedanken experiments') rather than by in effect 'acting out' (as the psychiatrists say), often with unfortunate consequences and sometimes with disastrous results. Using symbol systems, the modelling and simulation capabilities of people are important, as of course they also are with computer-based information systems.

Research on some aspects of this problem of optimizing Symbol Systems Access is being conducted within The University of North Carolina system. Professor Kenneth D. Shearer, Jr., of The North Carolina Central University campus within the UNC system, has published a number of papers in the general domain of linguistic geography (22-25). Those papers seek to lay out in a well-organized format the relevant informational resources available to us, as well as specific empirical data and inferencing from it, with reference to differences in access to certain forms of intellectual capital or knowledge or instantiated symbolism publicly available (e.g., in books and journals, in data bases and knowledge bases) as a function of which symbol systems or languages (e.g., French, or Formal Logic) one knows, or doesn't know (14). That is to say, given the fact that you know Chinese, for example, but not Montague Grammar, what is available to you and what is not in the way of the species's total accumulated store (intellectual capital) of Symbol System instantiations?

Initially, Kenneth Shearer was led to try to answer some of these questions in consequence of an experience he had a few years ago as a consultant on modern information systems and libraries for the government of Kuwait, when he observed that if a person knew only Arabic accessibility to children's literature was extremely restricted. Since then on a global basis he has generalized and systematized that kind of question, as well as the process of searching for answers to it. In doing so he has repeatedly emphasized the transcendent importance for SSA--transcendent relative to the boundaries of nation states--of the language communities to which people belong, the congeries of individuals knowing a specific symbol system or language, by comparison with the nation states of which they are citizens or residents. Unfortunately, such data as we have relative to these questions tends to be available only on the sometimes less relevant nation state basis, if at all.

The importance of that approach taken by Kenneth Shearer currently is being underscored by the migration of information sector jobs, or, alternatively put, symbol manipulative jobs (by contrast with, say, manufacturing jobs), from one nation state to another, provided there are users of the same symbol systems in both countries. The

presumption is that labor cost differences as between any such pair of nation states is sufficiently great to override the expenses of such a partial international transfer of business operations. Recently a highly visible instance of such a migration of symbol manipulative or information sector jobs has been taking place between the United States and Ireland. In Ireland in smaller cities 'trainers' are teaching local people with high school educations how to perform symbol-manipulative work roles in finance, in effect taking over from U.S. employees tasks which here often would imply an MBA degree. If those Irish citizens had known only Gaelic, as would have been true of some of their ancestors, especially in the west of Ireland, their lack of access to a relevant symbol system (in this instance, English) would have precluded the possibility of such employment; it would not have been what we have denominated a post-possibility of their language learning. In a recent article in The New York Times it was noted not only that these Irish employees command less in the way of salary and total compensation than the Americans they are displacing, but also that, come hell or high water, their motivation to hold onto those jobs was far greater, owing to a lack of present and future alternative work force opportunities, in a land where the unemployment rate and the birth rate are both so comparatively high. From similar causes (the reserve work force problem), as well perhaps as owing to differences in the current distribution across the two cultures of certain personality traits, presumably primarily in consequence of divergences in child-rearing and other cultural patterns, the level of precision of execution of the work force tasks in question was much higher in Ireland than here.

For the Pacific region there is a special relevance of this Ireland-U.S. development, inasmuch as heretofore the economic functions that have migrated across the Pacific and elsewhere generally were not out of the information sector of the economy, were not symbol manipulative. The manufacture of clothing, automobiles, electronic appliances are cases in point, all of them not untypical of the first phase Industrial Revolution, even when in fact they are inventions of the past hundred years. By contrast with the migration of such 'blue collar' manufacturing roles as these, now it is evident that it is possible to move symbol manipulative jobs as well, as with tasks which have been performed in the U.S. by literate Anglophones now migrating across the Pacific to, say, the Philippines, or Singapore, or Hong Kong. But the significance of understanding the phenomena in question is by no means confined simply to the economic implications of workplace relocation; rather, we see, additionally, how the adaptability to new roles for the workforce within any language community in no small measure will follow from its history of access to instantiations of specific symbol systems (e.g., reading in English about business matters, or, in any language, reading in the literatures of technology and science). The impressive recent comparative regression as to numeracy and literacy of American students, vis-a-vis the students in other advanced industrialized nation states and even in some that are not very industrialized, could be taken as a disquieting or even alarming case in point, in that over the longer term and mid term the level of living in nation states where such a regressive development takes place can only be adversely affected by such relatively poor access to relevant symbol systems.
Reliability of data with reference to levels of numeracy and literacy has proved to be a serious research hurdle for Kenneth Shearer and others; generally, government education offices tend to inflate upward in their reportings on levels of literacy, and as to reliable data as to the accessibility (through public libraries, schools, private holdings, etc.) of books, computer-based information, and the like in which instantiations of the symbol systems are to be found, the wickets are far stickier.

Professor Raymond Carpenter at The University of North Carolina system's Chapel Hill campus, among a number of his research interests, only some of which are within this general domain, has published on the implications of the translation process for symbol system instantiations access (2). Working with printed documentation, some of it of course from the United Nations, as well with computer tapes, Professor Carpenter also has found the path to reliable conclusions strewn with obstacles. Nonetheless, and no doubt aided by his experience as a social science methodologist and as a member of the international committee on the standardization of library statistics, he has been able to arrive at the most accurate picture to date of the international 'balance of payments' between languages translated out of and into, between interlingual lenders and borrowers of symbol system instantiations in the form of printed texts. Raymond Carpenter's research has extended from gross total figures to breakdowns by category of literature (such as scientific or humanistic). While much of Raymond Carpenter's attention has in the nature of the case focussed on European languages, as also with Kenneth Shearer, he has as well directed his gaze to other parts of the globe, including so-called Third World communities. Perhaps even more than for Professor Shearer, there have been difficulties for Professor Carpenter to contend with, in that such relevant data as we have tends to be organized by nation state rather than by language. While for certain purposes that type of breakout is not only understandable but needed, in other respects that type of data reporting perpetuates the illusion of the significance of the political entity over against the significance of the

BEST COPY AVAILABLE

people(s), the population(s), for which it is but one form of more or less useful aggregation. In some instances the dimension of language community membership is the more significant (26), as we are currently seeing to be implicated in popular attempts at disaggregation in Eastern Europe (e.g., 'Yugoslavia') and at reaggregation in the Western Pacific (e.g., students and bureaucrats in 'North Korea' and 'South Korea'; also, the Chinese in Formosa vis-a-vis those on the mainland). To date the pace of transcendence, and/or dissolution, of nation state boundaries in the Pacific region has been notably slower than in some parts of Eastern and Central Europe, and probably even slower than Catalunian and Basque and Breton and Fleming and Scottish efforts in Western Europe. In Europe it is now widely apparent that for many economic functions the nation state idea has produced entities that are too small to be at all optimal, while it has produced entities that (in part owing to language community identifications) are too large for certain ethnic, psychological, and communicational functions. But growing Japanese economic hegemonization in the Pacific (and globally ?) may come to speed the pace of revelation there too of the permeability of nation state boundaries, and a heightened, complementary sense of the significance of language use as an alternative type of cleavage plane among people. (There is an ironic footnote to be found in the fact that sometimes Serbian and Croatian are taught as though they were one language, Serbo-Croatian, rather after the manner of sometimes teaching Danish and upper register Norwegian as though they were but parts of one language, 'Scandinavian.')

Japanese leadership in machine translation--if not as to the prerequisite linguistic research (pace Professor Nagao), at least as to number of MT systems in place and, by some criteria, functional--may be interpreted as an index of the isolation of speakers of only Japanese from users of other symbol systems, many of whom are present or potential customers and trading partners for Japan. Other considerations apart, these economic motivations are powerful vectors for driving Japanese interest in such developments as automatic speech-to-speech translation systems as may come to be realized in telephonic communications. Such systems would be notable as, inter alia, creators of potential, and transient, and dynamic virtual symbol systems access. Machine translation, whether of the traditional textual or of the prospective oral variety, is at least in principle a partial technological fix of a very powerful sort for some problems produced by limitations in symbol systems access which techniques of conventional schooling in languages have not provided an adequate solution to anywhere. Nor is language teaching ever likely to, given the sheer number of languages to learn and the speed and degree of economic and communicational integration on a global scale; even the language learning record of such high achievers as, say, the Dutch does not, practically speaking, promise much with reference to Swahili, Chinese, Russian, Arabic, Hindi, etc., especially if one considers the existing workload of Dutch 'gymnasium' students. It may be apropos to suggest that for the Pacific region, and especially in larger time frames, one of the more salient dimensionalities affecting the rates of economic exchange and integration will be the infrastructural capacities for coping technologically with symbol systems access problems across linguistic boundaries. Interlingual mapping across symbol system semantic space differentials is a powerful emergent research concern (14), as discussed in a companion paper ("Interlingual Semantic Mapping") for this conference.

For our own research, the stars by which we seek to navigate include the optimization of symbol systems--as distinct from, and in addition to, the accessibility of instantiations of specific symbol systems. That is to say, we also are interested in how any given symbol system may be optimized relative to our emerging understanding of how the human brain and nervous system (and not excluding motor memory) conduct their computing (19); and, on the other side, we also are interested in the optimization of specific symbol systems relative to specific configurations of computer hardware/software/communications properties and to the already encoded knowledge which is to be input to the relevant computer-based information systems. Of course, some of these optimizations may be mutually incompatible, and a higher level trade-off optimization may have to be resorted to; also, re-examinations of the knowledge representation structures (10) and utilizations employed for public encoding of science and technology, etc., may lead to more adequate formulations of that knowledge, sometimes merely through freeing knowledge from no longer relevant dialectical and hermeneutic assumptions that were a part of the context of its initial emergence. An example of optimization of an intermediate symbol system--intermediate as between the symbol set of the symbol system, per se, and a specific use of it--would be with reference to a programming language, where in producing a revised version of it one would seek to make it generally more apt to the performance of some programming task(s), such as character level access for earlier versions of FORTRAN. Similarly with reference to natural languages: currently a research activity for us is trying to make it possible easily to convert English into an REL (Rapidly Extensible Language, or Lexicon), on the analogy of the aspirations for the REL movement of twenty to twenty-five years back apropos programming languages. More specifically, in another research effort, we are studying how automatically to add at the

appropriate nodes (8) new terms to a general purpose, conceptually organized thesaurus, such as Roget's; a new grant (for research on "Foundational Knowledge Representation for Knowledge-Based Systems") from The National Science Foundation (Knowledge Models and Cognitive Systems Program) should facilitate that work during the next several years. An example of what we are tackling is the achievement in specific sublexicons of finer granularity, of more discriminating lexical subpartitioning in sectors of a whole language's total semantic space, of higher resolution semantic discrimination through the automatic introduction and placement of neologisms as required.

Over the still longer term, we also are guiding our research by an aspiration to make it possible automatically to re-encode the content of books so that they may be employed as knowledge bases, as for use in Expert Systems (15). The current practice of building anew expert systems and their underlying knowledge bases one by one, as by analogy was done in weaving when accomplished by handlooms before the Industrial Revolution, seems needlessly inefficient when one considers the implications of extensions of Montague Grammars into Extended Phrase Structure Grammars, as well as other developments (e.g., Unification Categorial Grammars; lattices as knowledge representation structures [Zellig Harris; Rudolf Willie and his associates on the mathematics faculty at the Technische Hochschule Darmstadt]; John McCarthy and others re 1st Order Predicate Calculus), which taken together are leading toward the possibility of formally converting running text into an interlingual form such as may be used in logic programming. The recent achievement of spectacular gains as to compaction in data storage, such that, with the single atom switch technology, in principle the entire contents of the books in The Library of Congress can be placed on one silicon disk twelve inches in diameter, is a strong motivation for research on how automatically to convert book-length language strings into expert systems, insofar as those strings embody expertness.

The great bulk of the content of courses offered in universities in the Pacific region as well as elsewhere is instantial of symbol systems, whether used in oral form (e.g., lectures) or in printed form (e.g., reading assignments in books, on CRT displays). Put most comprehensively, what we are concerned to do with this utilization of extended Petri Nets is so to enable the coordination of experiences of instantiated symbol systems in a variety of languages, both natural and formal(ized), as to make it possible for people enrolled in universities or in more deinstitutionalized settings ("distance education") to achieve coherence in their intellectual and academic experiences. Again, the precedental significance of what

is happening in Europe--especially Western and Central Europe--is very considerable for the Pacific area. What has happened in the United States and with the EC will happen more often in "the new Europe" as a whole. Increasingly we may expect to see students transfer with far greater frequency than heretofore from one institution to another during the course of their studies--in part in consequence of the increased integration of the global economy, so that, job opportunities beckoning, students combining work with education may move to other schools. More and more that may be expected to happen even across national boundaries. In the Pacific region further facilitated there by the fact that current broadcast technologies employed for distance education are especially well-suited to the patterns of population distribution in Indonesia and Alaska and other Pacific territories, so that a useful infrastructure for distributed education may be more likely to be already in place there than in a high population concentration setting such as The Netherlands. And yet another important facet of the need for knowledge representation structures adequate to show relationality among components of intellectual experience and education is the need for literature conversability. In any Pacific region country, the United States, the problems attendant upon the lack of uniform national standards for licensure (as in medicine, law, nursing, etc.) may range [illegible] from [illegible] to [illegible] to [illegible] to

stressing intellectual and symbolistic interdependencies; some further implications of this work are brought out in our companion paper for this conference, wherein a similar methodology is directed at a related set of topics. As we have sought to make manifest in the course of this paper, the nature of the university scene in the Pacific region makes the results of our research seem especially applicable there.

result of low investment as a share of GDP in the sector.

(3) Large number of waiting applicants

Demand for telephone services had been growing especially in big cities. At the end of 1985, there existed 380,000 registered waiting applicants and 68,000 new applicants. The number was equal to about 70% of the total telephone main lines (602,000). The annual increase rate of waiting applicants from 1981-85 was about 30%. Potential demand seemed to be larger than this figure since many people were discouraged from applying for the service by the long waiting period.

(3) Unsatisfied grade of services

The system had not been facilitated in a good balanced manner. For example, the automatic telephone rate was as high as 90%, but the automatic exchange rate was 26%. A great portion of the long distance calls was handled by the operator assisted system. The switching, subscriber lines, and transmission capacities were not well balanced in many areas. As a result, call completion rate became low.

(4) Long delays in project completion

The completion rate of the third five year development plan was only one half of what had been planned to accomplish, and that of the fourth plan was estimated to be the same rate as the third plan. The greater part of the projects remained unfinished as carry over projects at every end of the plan periods.

(5) Shortage of investment fund

The capacity expansion plans in the fourth five year plan were to increase the capacity at the rate of 20% to accommodate the increasing number of waiting applicants. 60% of the investment fund, to carry out the fourth plan program, was raised from outside fund. The recent stagnation of the economy caused by declined oil prices makes the availability of investment funds difficult.

(6) Worsening financial performance

The revenue per telephone main line during the 1980-84 period had been increasing at the annual rate of 3% in real terms, while operating expenses in the same period increased by about 9% due to mainly the increase in staff salaries and wages, which grew at about 10% in real terms. Therefore, the increasing tendency of operating expenses should have been reduced to a lower level than that of revenues for future healthy management.

1.3 COMPARATIVE ANALYSES FROM EXPERIENCE OF COUNTRIES

One approach to determination of the appropriate balance between telecommunications supply and demand is to examine actual experience of countries in various stages of development.

The following indexes were utilized to compare the current status of various operating aspects as well as the socio economic environmental positions of seven countries during 1981-85 periods. The data was used from ITU published "Yearbook of Common Carrier Telecommunications Statistics, 1991 edition." The seven countries are Indonesia, India, Thailand, Malaysia, Singapore, Korea, and Japan.

A. Telephone main line per 100 population
B. Investments as a share of GDP (1/1000)
C. GDP per capita (1980 price in US$)
D. The ratio of telephone demand (the number of waiting applicants and new applicants) to the number of telephone main lines
E. The ratio of telephone supply rate (the incremental rate of telephone main lines from the previous year) to telephone demand
F. Total staff in telecommunication services per 1,000 telephone main lines
G. The ratio of operating expenses to total revenue from all telecommunication services

(1) GDP per capita: C and investment share: B

Scatter diagrams of these indexes, taken in pairs, are plotted as an aid in understanding the nature of the relationships between the indexes. Figure 1 is the scatter diagram of GDP per capita versus investment share. It is important to note that as GDP per capita increases, investment share increases sharply at first (like Malaysia), but it declines slowly (Singapore), and then, becomes constant (Japan). This shows that telecommunication investment needs more in the medium level of development stage.

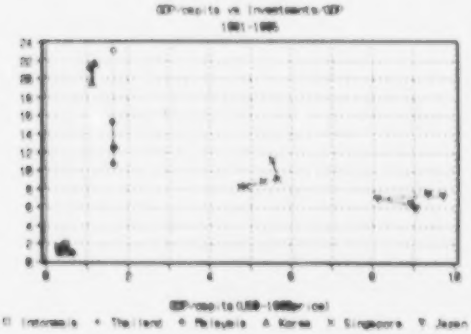

FIGURE 1 GDP PER CAPITA VS. INVESTMENT SHARE

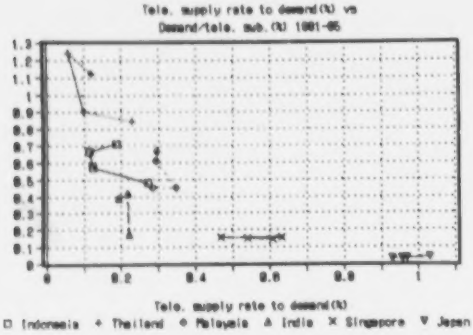
(2) The ratio of telephone supply rate to demand (%): E and the ratio of demand to telephone main line (%): D

Scatter diagrams of these indexes, taken in pairs, are plotted in Figure 2, which shows that in the initial stage, demand is lower as compared with telephone main line like Indonesia and India. But, as the supply rate increases slowly, demand increases sharply, and thus the ratio of supply rate to demand decreases, while the ratio of demand to telephone main line increases rapidly like Thailand. If investment share is to be increased to solve this situation enough to cover the increment pressure of demand, finally, the

2.11

continuous investment will increase the supply rate higher than the demand increase enable to meet almost 100% of demand every year like Japan.



Tele. supply rate to demand(%) vs
Demand/tele. sub.(%) 1981-85
Tele. supply rate to demand(%)
□ Indonesia + Thailand ◇ Malaysia △ India × Singapore ▽ Japan

FIGURE 2 THE RATIO OF TELEPHONE SUPPLY RATE TO DEMAND VS. THE RATIO OF DEMAND TO TELEPHONE MAIN LINE

(3) Total staff per 1,000 telephone main lines: F and the ratio of operating expenses to total revenue: G

Scatter diagrams of these indexes, taken in pairs, are plotted in Figure 3, which shows that the ratio of operating expenses to revenue becomes lower as the number of staff per 1,000 main lines decreases. This means that productivity increase will bring about better financial results.

It is noticeable that if investment increases to meet the demand, the operating entity should have such measures as reducing operating expenses as much as possible since depreciation and interest payment amounts increase so rapidly due to the large investment. This is a sign of lower ratios shown in the case of Thailand and Malaysia.

(4) Telephone density: A and staff per 1,000 main lines: F

Scatter diagrams of these indexes, taken in pairs, are plotted in Figure 4, which shows that productivity increases according to the increase of telephone density.

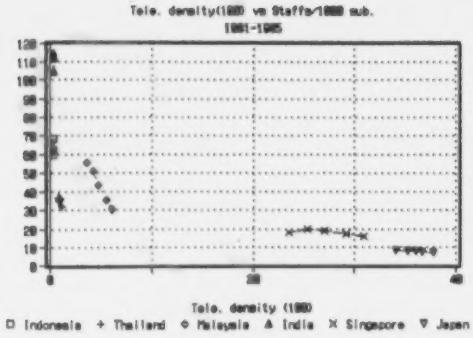

FIGURE 4 TELEPHONE DENSITY VS. STAFF PER 1,000 MAIN LINES

3.4 TWO COUNTRIES COMPARISON OF THE INDEXES

Radar charts of these 7 indexes from A-G for two countries comparison are drawn in Figure 5 for Indonesia, and Thailand, in Figure 6 for Indonesia, and Malaysia, in Figure 7 for Indonesia, and Singapore, in Figure 8 for Indonesia, and Japan. According to those figures, if we regard these countries as future development stages of Indonesia with respect of different level of GDP per capita, we can see four stages with numerical comparisons following from Thailand, Malaysia, Singapore, and Japan.

(1) The first stage

The ratio of operating expense to revenue can be reduced by increasing productivity to take such measures as reducing staff per 1,000 telephone main lines and start to increase investments that enable the speedup of telephone supply.

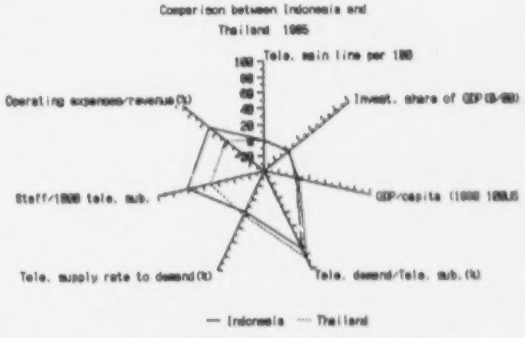

FIGURE 5 COMPARISON WITH THAILAND

(2) The second stage

Large investments will turn to be larger amount of depreciation and interest payments, thus, operating expenses should be reduced enough to cover those amounts. Due to large investment, the ratio of telephone demand to telephone main line starts to decrease since the telephone supply rate is increased over that of demand. We may say this is the first critical mass (CM).

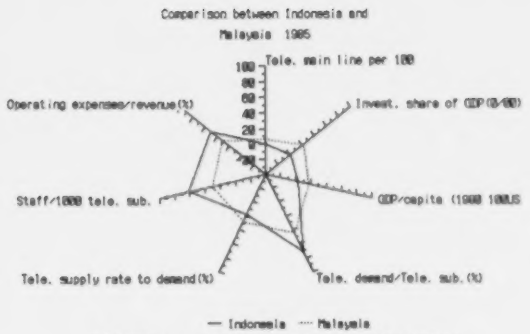

FIGURE 6 COMPARISON WITH MALAYSIA

(3) The third stage

Though investment amount increases continuously, the investment as a share of GDP will keep constant since GDP per capita increases higher than that. Telephone supply rate increases so rapidly, and eliminates the past high pressure of demand than that of the second stage since we passed CM period.

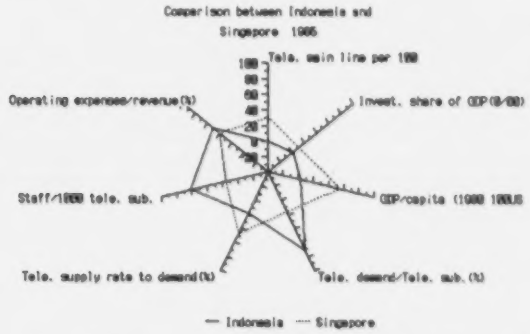

FIGURE 7 COMPARISON WITH SINGAPORE

(4) The fourth stage

The telephone supply increases continuously, and we finally reach the meeting point of demand and supply. Thus, we can supply 100% of demand every year. The age of Plain Old Telephone Service will end and a new era starts.

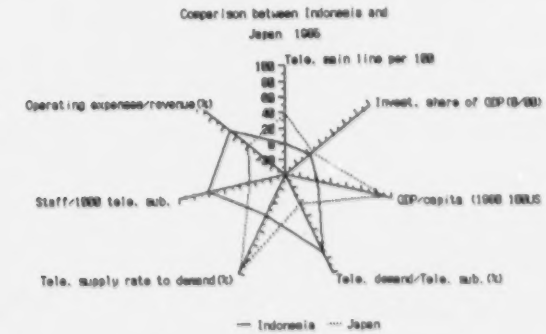

FIGURE 8 COMPARISON WITH JAPAN

4. DEVELOPMENT TARGETS AND STRATEGIES

4.1 DEVELOPMENT TARGETS

(1) Telephone density

The figure of telephone density is a key index of the country's level of telecommunications development. Thus, it is very important to increase this figure by accelerating the increase of the supply rate.

(2) Waiting periods for subscription

This figure also shows the level of the supply rate. To eliminate the waiting list, we should supply the numbers exceeding the increase rate of demand with careful consideration of priority given to area and user categories.

(3) Service standards

Service standards are the provision of automatic dialing or the increase of call completion rates.

4.2 DEVELOPMENT STRATEGIES

(1) Investment strategies

A. Service categories

Present main services consist of telephone and telex. However, it is possible to introduce other non-voice services in urban areas.

B. User categories

The first priority of the service provision goes to the business and official use customers. In urban areas, some of residential demands should be also satisfied.

C. Network coverage

At present, public telecommunications network is extended only to big cities. Thus, it is difficult for many people living on the outskirts of big cities to access telecommunications services. To realize the national development plans, it is essential to provide to all persons within a walking distance.

D. Supply rate

This is the incremental rate of telephone supply number as compared with the previous year. If this rate increases year by year, we may say the supply speed becomes up.

E. Regional priority

The government usually makes a plan given to priority by each region. To fulfill the plan, we should follow this regional priority. There is a contradiction between profitability and regionally balanced development.

(2) Operation strategies

A. Financial strategies

The structure of money inflow and outflow is

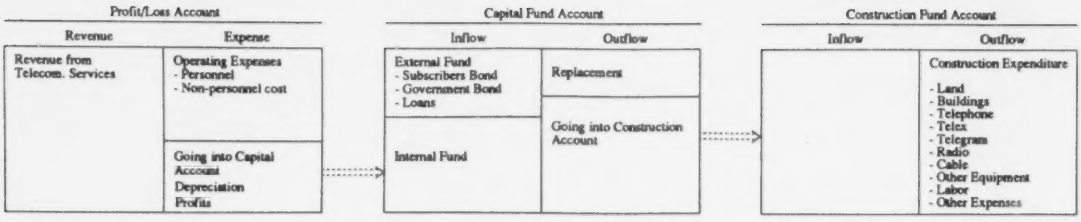

FIGURE 9 FINANCIAL STRUCTURE

explained in Figure 9. Important financial statements are three shown in Figure 9, which are interrelated to each other. It is noticeable that the amount of investment is determined by the amount of internal fund, which is composed of net profits, depreciation, and equity being invested by the government. Thus, if we can increase the internal fund by reducing operating expenses, we can increase the amount of external fund which is determined by that of the internal fund shown by repayment capability. The simple method to increase the level of investment as a share of GDP is to increase internal fund by adopting the internal management strategies.

B. Tariff strategies

PERUMUTEL's overall tariffs were higher than mean value in the Asian countries. Average telephone revenue per telephone main line in 1985 was recorded to be US$847. Present tariff systems were designed to cover the operating expenses. However, the new system can be proposed to create sufficient internal fund, and then, expand the capacity to eliminate huge waiting applicants, imp'ementing such new measures as discriminating business and residential user fares, or reexamining the current zone classification for call charges.

C. Manpower development strategies

One of the criteria which are generally used in judging efficiency of manpower of telecommunications service provider is the number of staff involved per 1,000 line units. When the figure of staff per 1,000 telephone main lines is compared with that of the other countries, the figure of Indonesia seemed high. A simple comparison does not necessarily represent a real picture. Indonesia's tough geography and needs for creating employment opportunities must be considered. However, the most productive level of manpower should be realized in quantity and quality.

5. DEVELOPMENT OF STRATEGY SIMULATION MODEL

5.1 INTRODUCTION

The PERUMUTEL corporate model had been developed as a planning tool to assist decision makings on long-term investment projects. The model consists of a system of statistical equations which were estimated by using the operating data of PERUMUTEL from 1981-84.

The aspects to be modeled are:
(1) the demand for the services and the revenue estimation,
(2) the service provision and estimation of operating expenses,
(3) the investment planning and estimation of fund size required and its sources, and
(4) the profits.

These aspects are incorporated into sales, manpower, production, investment, fund, and profit management in actual planning.

5.2 THE STRUCTURE OF THE SIMULATION MODEL

Figure 10 shows the flowchart of the model. First, the amount of newly created capacity to the PERUMUTEL system in period t (DCAPt) is given to the model as the first exogenous variable. Then, the amount of total capacity of the PERUMUTEL in the period t (CAPt) is determined with the amount of total available capacity in period t-1 (CAPt-1) and DCAPt.

CAPt is, then, distributed among 12 regional offices (WITELs). This decision can be made by the model operator exogenously. The amount of total available capacity of the i-th WITEL in period t is determined.

The number of telephone service (Sit), telex service (SXit), and data communication service (SDit) subscribers are determined by the subscriber demand functions of the telex and data communication services. The traffic volume of telephone service (XTXijt), telegraph service (TLGit), and Telex (XTXit) are calculated by the traffic models of these services.

The revenue (Rit and Rt) are, then, calculated by the tariff rates/fares (PIit, PMit, PCit), the subscribers and the traffic volume. At the same time, the personnel (PCit) and non-personnel operation (NPCit) expenses (O&M Costs) are derived from the personnel and non-personnel expenses functions, and the telegraph traffic. It is also possible to derive the number of staff in the i-th WITEL from PCit by the average wage.

Depreciation expenses, interest payment, and tax are calculated from the investment amounts, and the earnings before tax are calculated from the above revenue and operating expenses.

As an independent module of the above flow, the number of people who desire to start subscribing the telephone service (Dit) is estimated by the telephone service demand subscriber demand function. The number of the waiting applicants at the end of period t-1 (Wt-1) plus the number of new applicants in period t as new demand in pe-

FIGURE 10 FLOWCHART OF THE STRATEGIES SIMULATION MODEL

riod t is determined by the size of population (Nit), the level of income (Yit), the number of telephone services subscribers at the end of period t-1 (St-1) and the real subscription fare (PIit). At the end of periods t, the number of waiting applicants (Wit) will be derived from the difference between Dit (=Wit-1+NAit) and Sit.

As another independent module, necessary amounts of various investment funds, which are induced by the addition of new capacity, are estimated. New investments for the accommodation of new capacity are calculated as exogenous variables.

Finally, the amount of the net earnings, subtracted by depreciation, interest, and tax payments, is figured out. These figures are compared with the amount of investment for a financial evaluation, and then, how much amount of the external/outside fund (OFt) is needed to carry out the investment projects. The schedules of various OFt's are presented for the entire project periods for different combinations of the policy variables.

5.3 THE SPECIFICATION OF THE MODEL

(1) Telephone service subscriber demand

The new subscriber demand function for 12 WITEL areas is as follows:

$$Dit/(Nit-Sit-1)=0.1365+0.7773*(S/N)it-1 -0.0108*PIit+0.00008*Yit$$

where
PIit: Real installation fee of WITEL i in period t
Yit: Real income (GDP) of WITEL i area in t
Sit-1: The number of subscribers in WITEL i at the end of period t-1
Nit: Population of WITEL i area in t

(2) Telex service subscriber demand

The estimated model for Indonesia is as follows:

$$Log(SX/S)=-1.7934+0.72074*log(SX/S)t-1-0.03506* log(SD/S)t-1+0.35164*ID$$

where
SX: No. of telex service subscribers (1,000)
S: No. of telephone service subscribers (1,000)
SD: No. of data terminals (1,000)
ID=1 for Indonesia
=0 for other countries

(3) Data communication service subscriber demand

The estimated model for Indonesia is as follows:

$$Log(SD)=-8.7778+(0.7707+0.11487*TD)*log(S) +3.1724*ID$$

where
TD: Telephone density per 100 population
S: No. of telephone service subscribers (1,000)
SD: No. of data terminals (1,000)
ID=1 for Indonesia
=0 for other countries

(4) Telephone service traffic

The estimated traffic model for inter-province is as follows:

Log(XTPij)=-4.31559+0.61196*log(Sj)+0.51539*
log(Si)-(1.7117-0.1092*D8RS)*log(Pij)

where
XTPij: The volume of traffic of the telephone service from the i-th province to the j-th province in period t
Pij: Pulse per minute from i-th to j-th province
D8RS=1 for if the traffic is between Sumatera Utara, Sumatera Barat, Sumatera Selatan, DKI Jakarta, Jawa Barat, Jawa Tengah, DI Yogyakarta, Jawa Timur
=0 for others

(5) Telegraph service traffic

The estimated model for Indonesia is as follows:

TLGit=-137.636+(12.236+5.2345*TDit)*Nit
+(0.33045-1.4697*TDit)*Yit

where
TLG: No. of domestic telegrams (10^5)
N: Population (10^6)
TD: Telephone density per 100 population
Y: Real GDP of 1980 price in US dollars (10^9)
ID=1 for Indonesia
=0 for other countries

(6) Telex service traffic

The estimated model for inter-province is as follows:

Log(XTXit)=6.2730+[0.36966+0.06061*(Y/N)it]*
log(SXit)

where
XTXit: No. of pulses in the i-th province in period t (10^5)
Nit: Population (10^6)
Yit: Real GDP of 1975 price in Rp. (10^9)
SXit: No. of telex service subscribers

(7) Operating expenses functions

Personnel expenses (PC) and non-personnel expenses (NPC) for WITELs and headquarters are estimated as follows:

Log(PCit)=-7.8904+0.58137*log(Sit)+0.46621*
log(TLGit)+0.4933*log(SXit)
-2.9141*DHQ+WITEL Dummies

Log(NPCit)=-12.1103+0.62486*log(Sit)+0.87236*
log(TLGit)+0.28314*log(PCit)
-0.6705*DHQ+WITEL Dummies

where
DHQ=1 for Headquarters

(8) Gross earnings (GE)

Gross earnings (real terms) in WITEL i are estimated as follows:

GEit = Rit - PCit - NPCit

where
Rit: Real revenue amount in the i-th WITEL in period t

Gross earnings (real terms) for PERUMUTEL are calculated as follows:

GEt = GEit

(9) Net earnings

Net earnings (real terms) for PERUMUTEL are calculated as follows:

NEt = GEt - DCTt - ICTt - TCTt

where
DCTt: Real depreciation amount in period t
ICTt: Real interest payment amount in period t
TCTt: Real tax payment in period t

(10) External/outside fund

Real external/outside fund (OF) to be raised for PERUMUTEL is calculated as follows:

OF = FRt*(NEt+DCTt)

where
FRt: The ratio of raising internal and external fund

6. SIMULATION RESULTS OF STRATEGIC DEVELOPMENT

For the simulation, important variables for examining through experiments to understand a few possible future prospects are as follows:

A. GDP per capita
B. Tariff rates
C. Annual telecommunications service supply volume
D. Regional/area priority
E. Productivity increase
F. Diversification of funds source

The impacts of the above variables changes on PERUMUTEL can be evaluated by the financial profitability indexes shown in Figure 11, and then, we can figure out their feasible combinations of actual numerals for the formulation of development plans.

6.1 SUPPLY VOLUME

By examining a supply volume of the telephone, the relationship between telephone density and national income (GDP/GNP) per capita of countries in the whole world can plot a statistical line which shows an average supply volume for a given level of GDP per capita is usually utilized for the purpose of setting targets level of development in many countries. In the past, Indonesia experienced far below this average line due to low investments. Thus, the primary targets should be to catch up with the other Asian countries. Supply volume should be regarded as the most important figure. We may set two targets of supply volume according to the estimates of future GDP growth rates, that are, Plan 1 (low

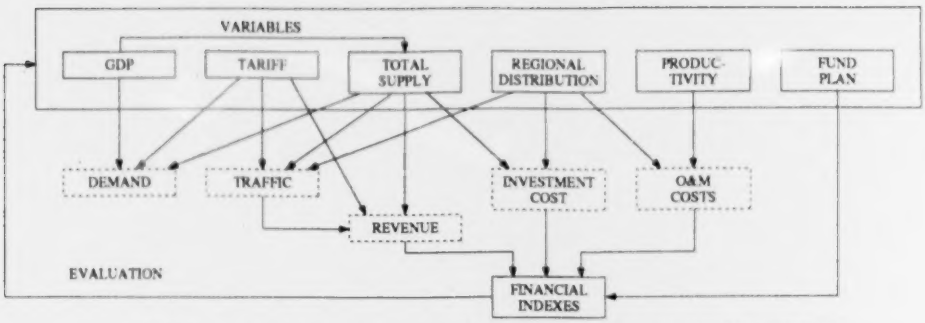

FIGURE 11 IMPACTS OF VARIABLES CHANGES ON THE FINANCIAL INDEXES

supply volume as a result of low GDP), and Plan 2 (high supply volume as a result of high GDP).

6.2 REGIONAL/AREA PRIORITY

Strategies can be classified into past policies to follow in the future (strategy A2), and, the new policies such stressing more on financial profitability, that is, investing more on urban areas and business use (strategy A1), or stressing on the balanced development, that is, investing more on rural areas and residential use (strategy A3).

6.3 PRODUCTIVITY INCREASE

Strategies such as manpower development to increase productivity are very important for the increase of investment. We may take three types of strategies and their applied results are expected to be M1 (best), M2 (second best), and M3 (most likely)

6.4 TARIFF CHANGES

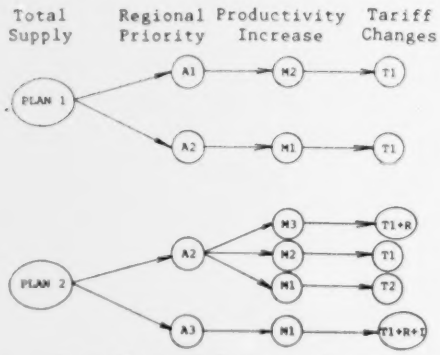
Since tariff rates were regulated by the government, only opportunity to increase the tariff rate is to meet the deficits happened by uncontrollable incidents. However, we may set our strategies of T1 (raise call fee), T2 (raise call fee slightly), T3 (unchanged call fee), R (raise annual rental fee), and I (installation fees) for experiments of our simulation model.

6.5 EVALUATION OF STRATEGIES

If the provider expects lower GDP and chooses Plan 1, the feasible combinations of either strategy A1 or A2 as its regional/area priority policy, the strategy M1 for the productivity increase, and the strategy T1 for the tariff changes, will satisfy the financial criterion.

If the provider expects higher GDP and chooses Plan 2, three feasible combinations of strategies will satisfy the financial criterion for the strategy A2. Those are i) the combination of M3 and T1+R, M2 and T1, M1 and T2. For the strategy A3, only one combination, M1 and T1+R+I, can satisfy the criterion.

The selection process for the combination of strategies is shown in Figure 12.



A1: Capacity expansion in major cities
A2: Capacity expansion in line with the past capacity expansion
A3: Equal capacity expansion in all
M1: Best (e.g., to realize 20 staff/1,000LU)
M2: Second best (e.g., realize 30 staff/1,000LU)
M3: Most likely (e.g., realize 40 staff/1,000LU)
T1+R+I: Increase of call, rental, installation fees
T1+R: Increase of call and annual rental fees
T1: Increase of call fee annual
T2: Slight increase of call fee

FIGURES 12 FEASIBLE COMBINATION OF STRATEGIES

7. CONCLUSION

Since telecommunications can provide more efficient but less expensive means of communication, a good network is essential to Indonesia, where transport costs are high due to the geography, enables people to disperse industry to the regional cities by attracting private investments, and enables people to hasten national integration among widely diversed population.

Corporate simulation model is a planning tool to assist decision makings on long-term investment projects. Decision makers can examine what will happen to the telecommunication sector if they continue to employ the current policies. A wide range of possible future prospects can be examined so that they can make advanced preparations to formulate optimum development plans by extracting feasible combinations of strategies for a given development target.

ABSTRACT

Even when people do not share a common language, computer-based information technology can be employed to lower language barriers in interpersonal communication--in the Pacific, and elsewhere. Short of machine translation (MT), one approach to such communication-barrier reduction is by way of the science of whole-language semantic characterization.

Perhaps someday any one of us will be able to speak into a microphone attached to a computer and receive a response, without regard to the language of the speaker or of the respondent. That day probably will not come very soon, despite the heavy funding being expended on speech understanding and generation in the United States and in Japan, to name two major supporters of such efforts. In an up-beat article appearing in the The New York Times on last August 14, Glen Rifkin (1991) pointed to systems which understand commands such as "Give me a list of all airports in Tunisia" and respond with a list of airport locations, or, in another example, a user says "I want to fly from Boston to San Francisco on July 4. What flights are available?" Again, information is displayed on a computer screen in response to the request. Such systems as these, the former being developed by Bolt, Beranek, and Newman, Inc., and the latter by Stanford Research International, are thought to be prototypes of the future of computing--a future which in this case is concerned with the "free interaction of the computer by voice" (Rudnicky, in Rifkin, 1991). Although such programs may indeed represent steps in the direction of such free interaction between voice and computer, clearly, because of their restriction to very limited domains of discourse, they are tiny steps. Also these programs have no design component dealing with translation (MT) between different natural languages, such as English and Japanese. Rather, these programs focus solely upon communication between a human voice and a computer. This type of communication, though, is also seen as a step toward spoken interaction between natural language speakers who do not share the same natural language.

But exchanges among language users content to use written input and output on computer screens and/or computer printers are closer to hand. Indeed, there is already a great deal of material which is translated from one language to another solely by machine, but the quality of those translations is generally not high enough to facilitate easy exchanges, even though basic understanding may occur.

Whatever form interpersonal communication takes--either spoken or written--an interlingual mapping [Linguistic Equivalence] from the meaning of the words and phrases in one language to those in another language necessarily must take place. It is with an eye toward facilitating that interlingual mapping that one focus on our research is directed. Our concern is to try to characterize the semantic spaces and subspaces [partitionings] of whole languages such as English. Given such characterizations for natural languages, it then would be possible to see what the fit is between and among languages. To speak anecdotally, we all know that here in Hawaii it is not possible either in Polynesian languages or in English to discuss snow with the same degree of specificity and, in a sense, sophistication, as it is in languages used by circumpolar peoples. Thus, there is a lack of "fit" among the languages along this particular semantic dimension. As we all know from individual efforts to learn other languages, such lacks of fit are frequent. Even when there seems to be word-for-word correspondence, it often turns out that the words are used differently, and word senses especially differ. For example, even though there is a preposition "fur" in German which corresponds to "for" in English, and so on through a list of such prepositions, the actual usage of those prepositions differs greatly, i.e., where "for" might seem appropriate in English, "mit" for "with" might be used in German. At present, our own research to systematize (R. Wille, 1990) the analysis of semantic space for whole languages concentrates less upon function words such as prepositions than it does upon so-called content words. Function words long have been regarded as the province of scholars and scientists primarily interested in syntax--in the words binding together the components of sentences--and content words have been the concern of those of us

primarily focused upon semantics. But it is evident that syntax and semantic categories often make for false distinctions, and it certainly will be necessary to incorporate the meanings of function words such as prepositions into whole-language semantic characterizations (S. Sedelow, 1987).

Our own concern with content words stemmed from our desire to develop the ability to extract automatically organizing ideas or concepts from a document or text. Initially we concentrated upon English and we also decided to proceed associationally. That is, our hypothesis was that we don't understand a sentence by mentally referring to a dictionary definition for each word in the sentence and then somehow multiplying all those definitions together so as to get at the semantic interpretation of the sentence. Rather, we hypothesized that we understand strings of words through association. As infants and small children, we are taught to associate given words with given objects, and then we accept words as surrogates for objects and string them together into sentences such as "The lamp is on the table." In time, we may learn that the lamp on the table is different from the lamp a miner wears when moving through a mine shaft, although both lamps have characteristics in common. Thus, we create associative spaces which overlap in some ways and not in others; the lamp on the table and the miner's lamp both provide illumination, but they differ as to expected shape, location, and so on. Our interest in associational semantics as well as our interest in using the computer to extract organizing or major concepts from documents and texts prompted us to look for some kind of lexicon organized associationally and ranging over an entire language. I should stress here that we were seeking a computer-based system which would deal with documents in any subject which might be discussed in a language such as English. Hence, we were not interested in building the sort of system focussed upon, for example, when planes fly from Boston to San Francisco--which of course comprises a very limited domain. Thus, no toy or miniature lexicon would have been suitable for our purposes and we certainly didn't want to create afresh a lexicon for, e.g., the English language. Rather, we wanted a lexicon that had some established validity; that is, a lexicon which was widely used both through time and across geographical areas defined by the speaking of English. We have come to call such a lexicon "culturally-validated," meaning that it has been used by many people for many years to facilitate the understanding of language strings (sentences, etc.) in a given language. The obvious culturally-validated resource based upon association is a conceptual thesaurus, and not a dictionary. In a thesaurus, words are "defined" through their grouping with other semantically-related words. In a dictionary, of course, words are defined through a series of short sentences and examples of the use of a word through a phrase or clause. After a comparison of two thesauri and a synonym dictionary, we settled on Roget's International Thesaurus, 3rd edition (1962), and obtained permission from the publisher to put that version of the thesaurus into computer-accessible form. Having done so, we could of course use the thesaurus to work up lists of words closely related to words appearing in a text, and this is an approach used by some today who buy one of the thesauri available in computer-accessible form. Such thesauri often are set up alphabetically like dictionaries and their primary purpose is to assist people who are searching for an alternate to a word they have used too often in a paper or proposed speech. Roget's International Thesaurus is not organized like a dictionary. Rather, its explicit structure appears to be a hierarchy as in Figure 1:

```
Class Six: Intellect
   III. Communication of Ideas
     K. Written Language
       603. Book. Periodical
         603.7
           dictionary, wordbook, lexicon,
           vocabulary;
               dictionary
```

Figure 1

At the top level of the Thesaurus there are eight classes, of which Class Six: Intellect is one. At the second level, each of the classes is divided into sub-sections, designated by Roman numerals. These sections in turn are subdivided into categories designated by capital letters in the Roman alphabet, and within those divisions are levels designated by numbers (in the example, 603. Book. Periodical); there are 1040 of these categories in the Thesaurus. The 1040 categories are divided into paragraphs headed by an arabic number; these paragraphs are untitled, with the exception that some have a part-of-speech designation (e.g. Nouns) preceding the number. Within the paragraphs are groups of words linked by commas and bounded by semi-colons and, finally, at the bottom are the individual words. As you can guess from looking at the hierarchy, for the purpose of simply finding words closely related to a word in a text, we would look at the level bounded by a semicolon--in the example: "dictionary, wordbook, lexicon, vocabulary."

Almost immediately we wanted to do more than simply use the Thesaurus as a guide to words within a particular semantic subspace. We wanted to know how the Thesaurus, itself, was structured internally. Obviously, it included a hierarchy but what were the biases of the Thesaurus? Were some lexical areas more heavily represented than others? And,

if so, how could we go about discerning that? It also seemed to us that it ought to be possible to use the Thesaurus as an aid to automatic disambiguation--that is, we wanted the computer to determine, with the help of a thesaurus, what particular sense of a given word was being conveyed by a specific use of that word. In many languages, many words have more than one sense or meaning, and the users of any one language customarily have very little trouble disambiguating among those senses so as to zero in on the sense being used in a particular context. Intuitively, it seemed to us that a particular semantic subspace in the Thesaurus could be identified through the context in which a given word appeared, so that "arms" meaning parts of the body could be automatically distinguished from "arms" meaning military weapons. Clearly, in order to detect and explicate such relationships, a principled, rigorous way of moving around in the Thesaurus was necessary. One simply couldn't move around in a somewhat random fashion, hoping that associations might fall into place. The mathematical model developed by Robert Bryan (1973, 1974), once our doctoral student, provided the principled guide to the computer system seeking information in the Thesaurus. This model has been described not only in Bryan's original papers but in subsequent presentations directed to a variety of audiences. For the sake of clarity here, we will again provide a brief exposition of the model, with apologies to those of you have encountered it elsewhere.

The Bryan model is based upon Entries, Words, and Categories, all of which are formally defined. Intuitively, they are understandable through this T-Graph representation (Figure 2):

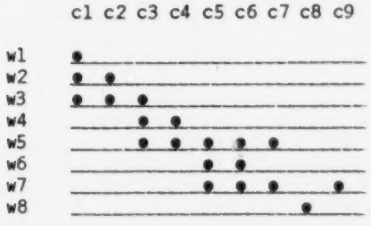

Figure 2

In this T-Graph above, the entries would be e11, e21, ...e88, the words would be the words would be w1 through w8, and the categories c1 through c9. Bryan also defines a Molecule, which consists of all the words and categories denoted by the entries. So that, if our set of entries were: (e11, e21, e22), the range of the molecule (the m-chain) for this set would be the set (w1, c1, w2, c2). The range of words would be the set (w1, w2) and the range of the categories the set (c1, c2).

To move around among the entries, no matter where they might occur (utilizing the multilocality property [possible for any given word], and thus obviating the need to refer exclusively to the explicit hierarchy), Bryan defined Chains, ranging from Type 1, the most general, to Type 10, the most restricted. For the purposes of our research, Type 9 and Type 10 chains have proved most promising, because they call for strongly-linked connectors--a situation in which at least two categories (in our research to date, the semi-colon groups were designated as the categories in question) contain more than one word in common, or at least two words contain more than one category in common, as in Figure 3:

657.2.1 route, itinerary, course, path, track, run, line, road;
273.5.2 progress, course, run
275.6.2 course, run, passage
391.5.2 melt, run, thaw, colliquate

Figure 3

As you see, the top three groupings of words are strongly linked, whereas the bottom group, in which the only link is "run" (and it clearly has a different sense, or meaning, from the closely related top three groups), is not strongly linked to any of the other groups shown in Figure 3.

As we had hoped, the Bryan model enabled the computer to automatically disambiguate among word senses. In a recent presentation to the Dictionary Society of North America, our student, Victor Jacuzzi (1991), described an approach which capitalized on Type 10 connectivities and produced groupings such as: "abstract, nonobjective" and, as another sense, "abstract, remove"; or, in another example: "absorption, assimilation, ingestion" as opposed to "absorption, engrossment, preoccupation." Earlier, Archie Patrick (1985), working with the subset of verbs in the Thesaurus, also produced computer programs which discriminated among homographs (words which are spelled in the same way, but have different senses). For example, his approach discriminated between "magnetize" in the sense of "electromagnetize" and "magnetize" in the sense of "hypnotize" and "mesmermize"; another example, "flower" meaning "flourish" as opposed to "flower" meaning "garland" and "wreathe."

Work such as that of Patrick and Jacuzzi, as well as recent work by Brady and Old, confirms our belief derived from earlier research using the Thesaurus that it mirrors (especially at lower hierarchy levels) very accurately the associational patterns used by English speakers for, among other processes,

interpersonal communication. In a paper presented at the Spring, 1991, sessions of the Midwest Artificial Intelligence Conference, Brady (1991) showed how to use Categorial Grammars in interaction with the Thesaurus to discriminate among word senses. This project was of particular interest because it compared very favorably with an effort by Kenneth Church, now at Bell Laboratories, and Patrick Hanks (1990) to use textual context for generating concordances which might be of use to dictionary constructors. Specifically, as to senses of the word "save," Church and Hanks grouped together under the sense "Save Person from Bad," the following:

1) to save Indian tribes from genocide at the hands of

2) to save him from undue trouble and loss of money

3) to save more powerful Democrats from harm

4) to save my five children from being burned to death

5) save us from sin

Under "Save Person from Bad Location," were:

6) save the toddler from an abandoned well

7) save two drowning boys from a turbulent creek

Brady's computational approach, using the Thesaurus, resulted in three divisions, rather than two, of the sentences above. His divisions were as follows: I. "Save Person from Killing/Death/Fluids," under which were grouped, from above, Sentence 1 (Blood Relationship, Thesaurus), and Sentence 4, 6, and 7 (Youngling, Thesaurus). Brady's second division was, from the Thesaurus, "Save Person from Inexpedience"; Sentence 2 above fell under this category. Brady's third Thesaurus-based division was "Save Person from Vice," which took care of Sentence 5 above. (Sentence 3 above fitted into another of Brady's divisions: "Save Plan/Politics/Association from Inexpedience/Failure," not discussed here.) As is evident, Brady's programs using context and the Thesaurus provided for more fine-grained distinction among word senses than did the Church and Hanks technique, based on co-occurrence of words in context, including 'markers' such as "from."

In a paper presented to the Dictionary Society of North America, another of our students, John Old (1991), showed how word senses align among the Thesaurus, the Oxford English Dictionary, and a study by the noted linguist, George Lakoff, and his student, Claudia Brugmann (1988), on the senses of the word "over." Very briefly, after analysis of quantities of data, Old noted that "over" meaning "across to" superimposed the senses of the definitions of "over" which are in the OED. "Across to" closely matched Brugman and Lakoff's choice of a central sense for "over," "above" + "across" and to the central sense of the "across"-containing semi-colon group in the Thesaurus. However, in the Thesaurus the central sense based on the number of links to other senses of "over" is "additionally." This comparison may suggest, among other things, that Lakoff and Brugmann depended upon dictionaries rather than Roget-style thesauri for at least part of their analysis. In any event, the strong overlap among all three categories of word senses further encourages us as to the validity of the Thesaurus.

All of the work cited thus far has concentrated upon the semantic spaces of a single language, English. We have conducted one study, involving English and Chinese, which has been reported upon elsewhere (J. Sedelow, 1987), but because it is germane to the meetings here, we will briefly cite some of the aspects of that study. For the Chinese component we relied upon Bernhard Karlgren's (1974) list of 5000 Chinese stems, or simplicia (represented in English by 6181 English words). Our approach was then to take the English words approximating each stem word and distribute them against the Thesaurus, to see how many "hits" we would get and what the patterns would be. The resulting pattern we took as support for the observation that Chinese, as well as other Oriental languages, places less emphasis upon semantic polarities, or opposites, than do Western languages. For example, "substantiality" had a hit rate of 3%, while its opposite, "unsubstantiality" registered only 11.95%. Here are figures for some other opposites: "relation" 17.05%, "irrelation" 8%; "similarity" 18.75%, "dissimilarity" 9.23%; "agreement" 22.76%, "disagreement" 5.95%; "superiority" (16.61%), "inferiority" 11.21%. Clearly, partitioning in Chinese differs from that in English, at least on the basis of the representation of those languages in the Karlgren simplicia and the Thesaurus.

For purposes of interlingual communication, we think it would be attractive to be able to pick words in one language and examine the path (as in a T-Graph) linking the words together and then perform the same exercise for the analogous words in the other language(s) involved. Differences in the paths ought to reveal something about differences in word senses, both at the obvious and at the subtle levels.

When we talk about semantic space and semantic subspaces, as well as about interlingual mapping, the notion of semantic distance--of closeness and lack of closeness among terms--seems implicit in such

A structured diagram that contains information for operations systems analysis is introduced. The diagram is called Operations Systems Analysis Information Diagram (OSAID) and includes five essential elements of telecommunications operations systems. An OSAID example of inward line trouble report and testing is illustrated; however, the methodology can be applied to other types of operations as well, such as service provisioning. Furthermore, in addition to being a method the diagram is also a modeling tool. An example of a queuing simulation model based on an OSAID diagram is given.

[illegible]

Operations systems (OSs) have been used to assist in the operations of telecommunications operations for more than two decades. Some important motives of having OS include the reduction of manual and paper works, reduction of processing time, and increasing efficiency. A result of using telecommunications OSs is automation, i.e., mechanization of operations (for customer service and network management). Meanwhile, centralization of work locations is another result. OSs have provided remote operations capabilities so that technicians can perform a wide range of work from a central location, such as trouble reporting and testing from a single customer service center.

Traditionally, operations systems are developed mainly for one organization's automation need. For example, most billing systems are developed for automatic bill printing and mailing; these usually do not have a feature such as real-time access to billing information for customers. Therefore, as the need for centralization and integration grows, it is expected that more complicated operations systems will be required to better streamline OS data dependencies and synchronizations to use shared data.

Because of the increasing use of new technologies to manage telecommunications operations and the presence of highly automated, intelligent, and stand-alone equipment or network elements, modern operations have to deal with information management to a much greater extent. Thus, in this paper, a simple diagram is introduced to help construct and analyze operations flows.

OSAID

Considering an OS as a processing system, in which either physical work or information is provided to perform certain OS function(s), is the basis of this diagram approach. A sub-process or step is to complete a task that will add value to the whole process. It can be either information processing or physical work. Basic elements for analyzing operations are, therefore, related to the components that affect the process. It is necessary to know what, who, and how to perform the work and its way of transformation (input and output). OSAID is a diagram (see Figure 1) in which five elements are centers onto designated positions of the a large box, which has an upper and lower rectangle. The upper part is used to name the operation. The lower part is divided into four small triangles; input and output are on the left and right, and organizations and data source are on the top and bottom. Figure 2 shows an OSAID of a inward line trouble reporting and testing process. For the illustration purpose, the example shows partial work flows and data sources. The five elements of OSAID are explained in the following:

1. Name of the operation - An operational process name, preferred to be short and descriptive, is given on the top of the diagram. For example, "Receiving Customer Trouble Report" is an appropriate operation name.

2. Task(s) to be accomplished - The key activities of an operation are listed. The activities will "add value" to the whole process. For example, " Talk to Customer A

Figure 1. Elements of OSAID

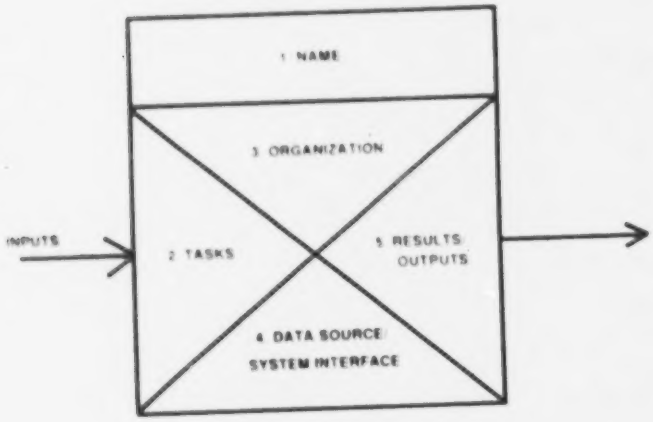

Figure 2. OSAID of a Special Service Testing Process (High-Level)

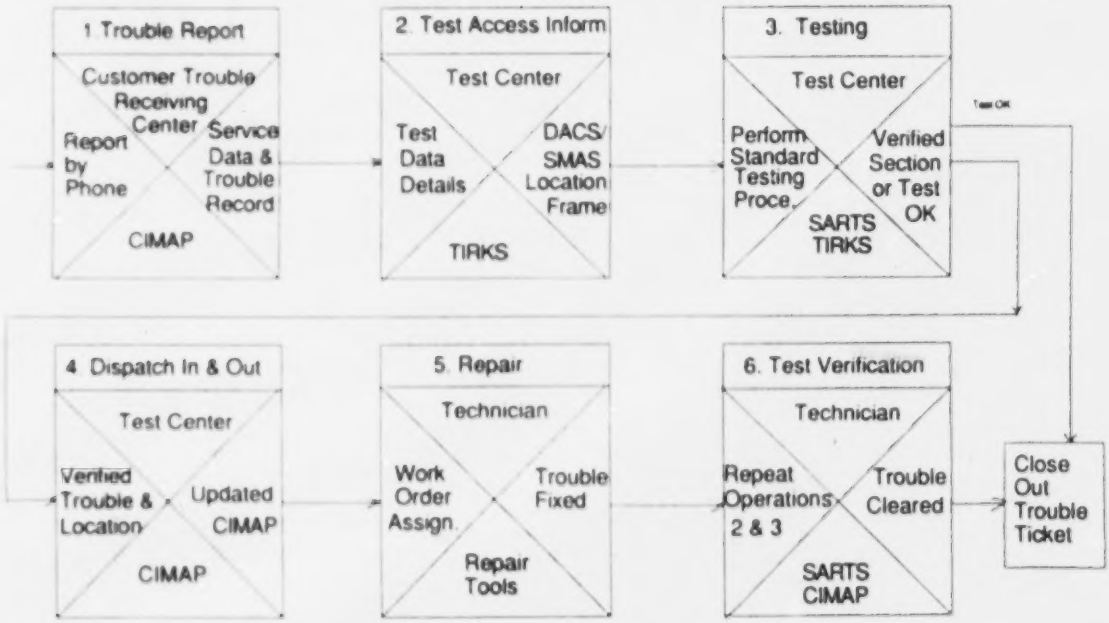

Generate Trouble Ticket" are value added activities in the "Receiving Trouble Report" operation.

3. Organization(s) responsible for the operation - The responsible organization is the work performer or information provider of an operation. Though, in many cases, the human-touch is unnecessary for performing a job, it is critical to know who is the responsible person (organization). For example, the customer service center may be an organization responsible for a leased line service's trouble report and testing.

4. Data source to support the work - Operations systems, files, databases, or records that support the completion of tasks are listed here. For example, the trunk records and remote testing systems are the main information sources needed for identifying service troubles.

5. Result/Output of the operation - The result of an operation, either physical work, document, or information, is the output of the process, and it usually becomes the input for the next operation. For example, the output of "Receiving Trouble Report" is an initial trouble ticket, which becomes an input for the next operation, "Trouble Isolation and Repair".

Although various kinds of diagraming methods have been used in the past, OSAID presents a structured way that is quiet easy to understand and to use. OSAID is an "operations oriented" diagraming methodology and can be useful by system planners, designers, developers, and operations staff.

In order to compare OSAID with other tools, two operations flow diagrams are illustrated in Figures 3 and 4. Figure 3 includes detail organization and system links shown together with the work flow process. It contains significant amount of information; however, this type of diagram is usually difficult to understand and explain. Figure 4 presents operational flows (rows) according to the corresponding organizations (columns). The data source information is not available in this type of diagram. In advanced operations environments, a diagram similar to Figure 4 is insufficient to show data source or system relations.

The following list is to characterize OSAID and includes its advantages.

- Standard Operations Diagram - OSAID can be considered as a common practice tool. Since it is relatively easy to construct and explain, the users can expect effective communications by using the methodology.
- Flexible Detail Level - The OSAID user determines the level of detail according to the information needed. However, it is important that the user knows and maintains the same level of detail for the entire process.
- Input-Output Concept - The diagram forces analysts to think of information or functions in the form of input and output. Via the diagram, one can assess the purpose or function of an operation based on the input/output relations.
- Value Added View - Due to the input-output concept built into the diagram, the value added by one operation can be identified based on the flow chart.
- Data Source/System Interface Information - The diagram provides clear data source/system interface information (name of the system or database and interfacing method). When automation and centralization are implemented widely, a centralized data source should appear throughout OSAID diagrams.
- Graphical Presentation - Identical to the form in Figure 1, computer graphics can be generated to represent any operations processes. Conceivably, a graphical presentation provides the benefits such as easy to use and flexible to change to those large scale and complicated systems.
- Computer Simulation - OSAID can be easily modified and becomes a waiting line (queuing) model. A simulation will require additional information , such as event occurrence and processing time patterns. An OSAID model can be extended directly for simulation. An example of using a General Purpose Simulation System (GPSS) package for simulation modeling is given in the next section.
- System Development Tool - OSAID can be an engineering tool used by system developers. The system developers will be better able to generate information/data flow diagrams and communicate with the customers (users). If

Figure 3. Operations Flow Model A

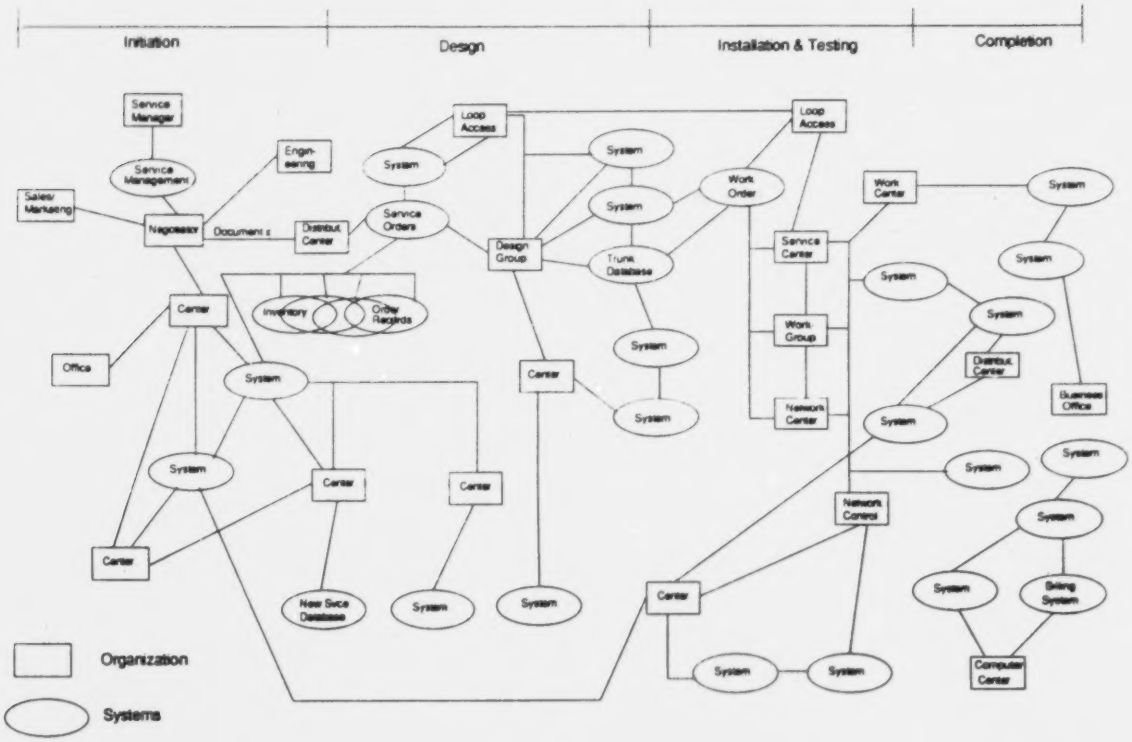

Figure 4. Operations Flow Model B

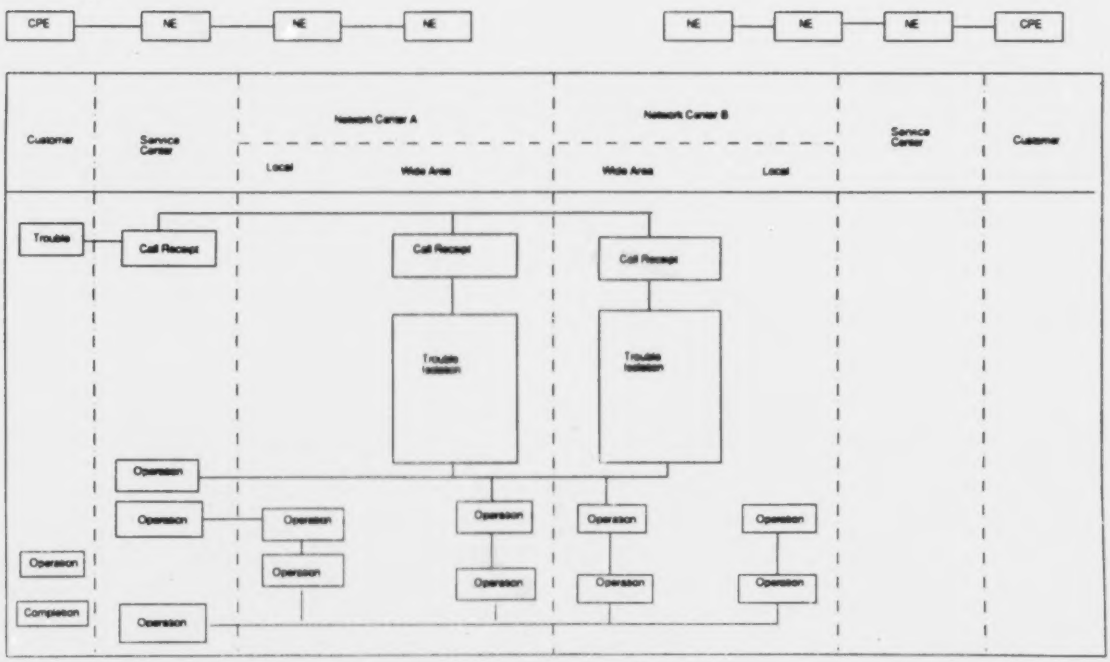

307

OSAID would be presented interactively in computer graphics, it would be easier to change configurations, features, interfaces, etc.

OPERATIONS SIMULATION

An example of simulation of a provisioning process, based on an OSAID model, is illustrated in this section. The purpose of this illustration is to show that information included in OSAID can be easily extended to simulation modeling. A typical queuing simulation requires the knowledge of "customer or arrival" and "server", which are the "input" and "organization" in OSAID. Additional data are needed for simulation; they are "arrival rate", "service rate", "number of servers", etc.

Figure 5 shows a special service provisioning processes described by an OSAID. A GPSS model, which has arbitrary assumptions of data, was constructed based on this diagram. Appendix A lists the GPSS program and Appendix B shows the results after a simulation run of the program. Because the main purpose of this example is to show the use of OSAID, the data and simulation results illustrated here are insignificant. Combining OSAID and simulation, the result can be very useful either for planning or improving operations processes. Simulation generates the results of resource utilization information, such as total processing time, waiting time at each "service station" or "organization". Furthermore, simulation can generate flexible operations plans under different scenarios or system configurations.

CONCLUSION

In order to understand operations processes, it is necessary to perform and practice a step-by-step analysis manually or on a computer. The OSAID methodology has been introduced to experienced and less-experienced operations planners. Experienced planners are able to better understand the methodology within a few minutes and then quickly provide information needed for OSAID. It takes about the same amount of time for less-experienced planners to understand the methodology; however, they need a little more time to construct an OSAID flow chart. Comments received from planners were mainly that the space limitation to draw the diagram itself and lack of computer graphics support.

The difficulty of space limitation has to be overcome by using more abbreviations and acronyms. As far as presenting OSAID on a PC or terminal, it is not difficult. Combining computer graphics for OSAID and simulation is really a challenge. Because of the ease of OSAID and the power of simulation, a new tool combining the two has the potential to become a very useful engineering tool. A simulation based on OSAID would deliver the following desirable results, in addition to the advantages already mentioned.

- Demonstrate quantitative benefits such as utilization levels,
- Explain changes in work processes and their impacts in a live model,
- Perform scenario analysis for different assumptions via simulation.

In order to realize if OSAID is highly valuable for operations planning, more experience should be gained in using the methodology. An organization will be benefited by widely practicing a common planning methodology such as this one. With its simplicity and flexibility, OSAID has the potential to be developed and become a tool for improving productivity of large-scale systems engineering.

INTRODUCTION TO FIRE PROTECTION EMERGENCY INFORMATION SYSTEM

Shuhei Onuki
FUJITSU LIMITED
Kawasaki, JAPAN

ABSTRACT

A variety of natural disasters such as earthquakes,floods,and typhoons and their potential impact on a highly dense and complex urban environment have made it crucial that such services as fire and disaster prevention be able to respond quickly and comprehensively as needed.

This paper discusses the role of information processing systems in helping to ensure this required response.

1. INTRODUCTION

Japan's fire prevention administration began with municipal fire protection agencies in March, 1948. Since then, its activities have come to include far more than five prevention -- first aid, rescue services, and disaster prevention measures.

Information communication technology in fire protection application entered the picture about ten years ago. Aid from the national government for municipal fire protection activities has increased annually. The number of municipal governments seeking to upgrade fire prevention and emergency information systems has also increased.

2. OVERVIEW OF FIRE PROTECTION EMERGENCY INFORMATION SYSTEMS

This chapter explains the components and outline of fire protection emergency information systems.

2.1 System Components

The purpose of the fire protection emergency information system is to help dispatch a fire fighting team when a fire is reported so that they can arrive as soon as possible. By providing accurate information as soon as possible,damage can be minimized.

The system is integrated and contains computers, communication equipment, and peripherals. The following subsystems are closely linked with each other:

- Command subsystem (reception and command controller, and station terminal equipment)
- Computer subsystem (command control computer and information processing computer)
- Map subsystem (site locating support)
- Radio subsystem (radio control console)
- Mobile communication subsystem (vehicle location, vehicle navigation, and mobile terminals)
- video subsystem (large screen at control center)

Figure 1 shows the system configuration.

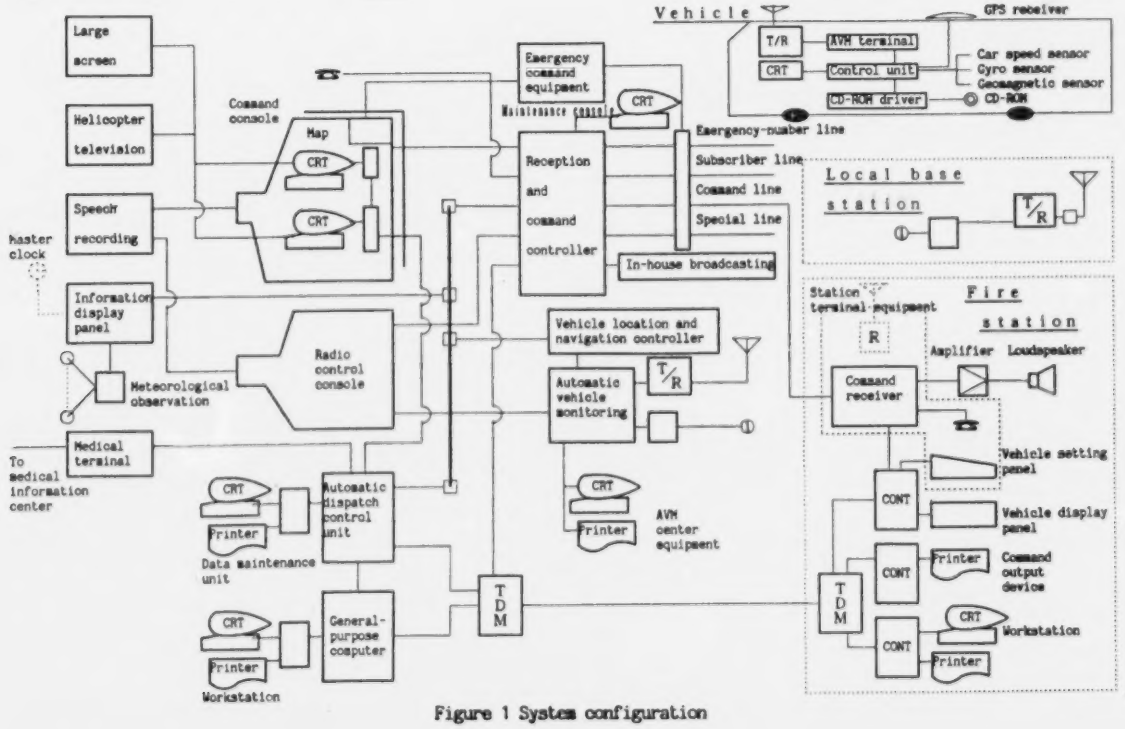

Figure 1 System configuration

2.2 Outline of Each Subsystem

The characteristics and functions of each subsystem are as follow:

(1) Command subsystem
This subsystem receives emergency-number calls and quickly sends commands to fire stations. It is an important function of the communication system.

(2) Computer subsystem
This system automatically assigns personnel and equipment to be dispatched according to the location and type of the disaster as well as disaster category information. It also supplies support information for protection activities from the fire protection information database.

(3) Map subsystem
This subsystem, displays a map of the area around the disaster when an emergency-number call is received thereby allowing the operator to pinpoint the site and determine what to do while speaking with the caller.

(4) Radio subsystem
This subsystem allows communication with the dispatched personnel. It is another important function of the communication system.

(5) Mobile communication subsystem
This subsystem allows information exchange between the center and vehicles (mobile terminals) through radio communication.

(6) Video subsystem
This subsystem displays monitors of the disaster site and computer-generated images on a large screen.

3. POINTS IN SYSTEM DESIGN

When systems engineers design fire protection emergency information systems, they must consider the following requirements:

- The fire fighting team must arrive quickly at the site.
- The information must always be accurate and up to date.
- The system must be easy to use.
- Useful support information must be quickly communicated to the fire fighters at the site.

These points are important because they affect the design of each subsystem for the integrated system.

These points are considered below.

(1) Quickness with which the team arrives at the site
The quicker the firefighting team can reach the site, the lesser the damage that is caused. This is important in system design.

(2) Accuracy of information
If the system keeps up-to-date information about the vehicles and other firefighting facilities, appropriate firefighting teams can be organized quickly when a disaster occurs. In addition, if the system has accurate information about the disaster site and other environmental conditions, the dispatched team can arrive quickly at the site. Important factors in system design include realtime collection of vehicle and other information, quick access to information stored in the center, and the building of a fire protection information database.

(3) Ease with which the system is handled
Operators must be able to handle emergency calls quickly and accurately. An important factor in system design is ergonomics.

(4) Usefulness of information supplied to the site
If up-to-date information is supplied to the site in a timely manner, the firefighting team can function more efficiently. An important factor in system design is the collection of data from a wide range of sources and a supply of dependable information obtained through analysis of source data.

The points discussed above are specific to fire protection emergency information systems. Reliability, flexibility, maintainability,and economy must also be considered for system design.

4. SYSTEM IMPLEMENTED FOR DISASTER PROTECTION

Systems engineers are always seeking the best systems using available technology. This section discusses the facilities we have implemented to fulfill the above purpose and the configuration of these system facilities.

(1) Quickness with which the team arrives at the site
We have designed and implemented a system for quick action with consideration on two points: (a) the precommand intended to start preparation for a dispatch as soon as a disaster notification comes and to dispatch a team quickly when the situation is confirmed as a disaster and (b) the dispatch command intended to allow checking of the disaster and other conditions before the team arrives at the site and to lead the team on the best route to the site.

(a) Precommands
Precommand messages are stored in the station terminal equipment. When the type of disaster and the nearest fire station are identified, the appropriate precommand message is selected to issue a precommand. Figure 2 shows the configuration for precommand issuance.

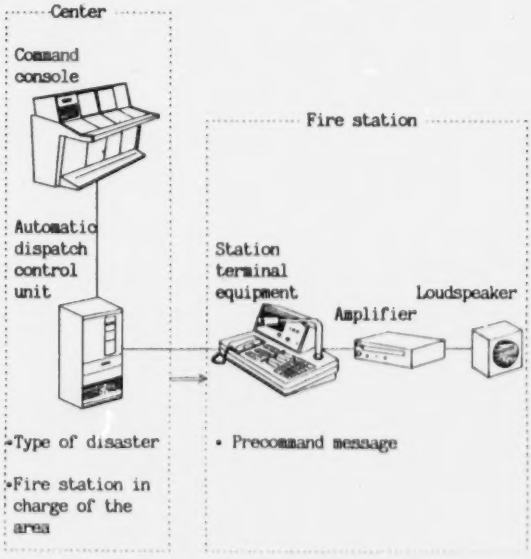

Figure 2 Configuration for precommand issuance

Precommand instance allows preparation for dispatch to start before the command is issued. This has reduced the dispatching time by five to ten seconds.

(b) Dispatch command
A command output device is installed at the fire station. When dispatching is decided on, command data is sent from the center to the fire station output device, which then outputs a dispatch command. Figure 3 shows the configuration for command output.

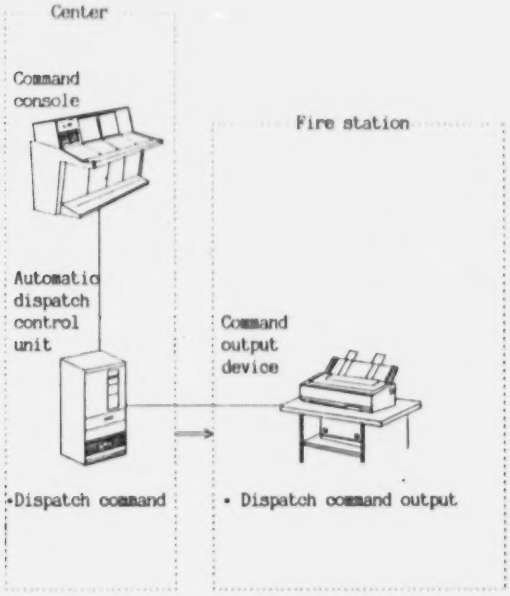

Figure 3 Configuration for dispatch command output

The output of a printed dispatch command enables people in the fire station to identify the type and location of the disaster through both voice and written instructions. A team can then be quickly dispatched.

(2) Accuracy of information
To fulfill this requirement, we designed the system featuring realtime data collection and a database considering two factors:(a) vehicle management intended to keep up-to-date information so that the most suitable equipment can be utilized when a disaster occurs and (b) support information management intended to keep information about the latest site and other conditions so that efficient dispatch and on-site activities can be assured.

(a) Vehicle management
An automatic vehicle monitoring (AVM) terminal is installed in each vehicle. It automatically transmits pertinent information about the vehicle to the center. Figure 4 shows the configuration for vehicle management.

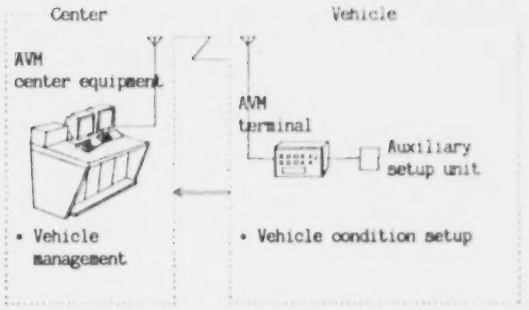

Figure 4 Configuration for vehicle management

This vehicle management feature using AVM assures detailed control of vehicles even when they are not waiting at fire stations so that teams can be organized appropriately in case of a disaster.

(b) Support information management
A workstation is installed in the fire station. Using this workstation, the fire protection information database can be accessed to update registered information, hydrant and water information, and other support information on a realtime basis. The system can thus assure the support information is up to date. Figure 5 shows the configuration for support information management.

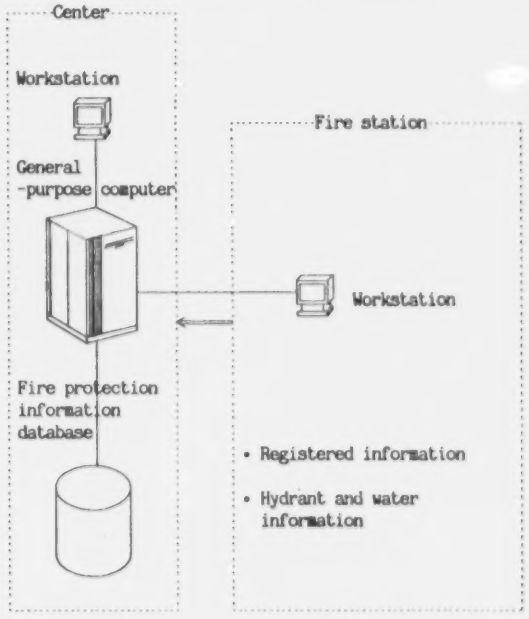

Figure 5 Configuration for support information management

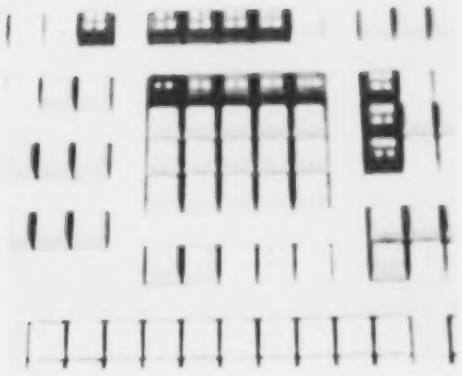
This support information management feature using workstation allows realtime information management and allows efficient preparation for disasters.

315



Photograph 1 Special keyboard

Photograph 2 Touch panel

(b) Plasma display
The condition of the emergency number lines can be checked at a glance on the plasma display. (See Photograph 3.)

(c) Usefulness of information supplied to the site
To fulfill this requirement, we developed (a) a tactics system designed so that video and other information can be collected and analyzed at the center and (b) a radio facsimile system designed to ensure that the results of analysis are quickly sent to the disaster site. These two features enable a wide variety of information to be collected and supplied.

(a) Tactics system
When a disaster occurs, a disaster administration board is established at the center in order to collect information from various sources and have the information analyzed by personnel of that board. Figure 6 shows the configuration of the tactics system.

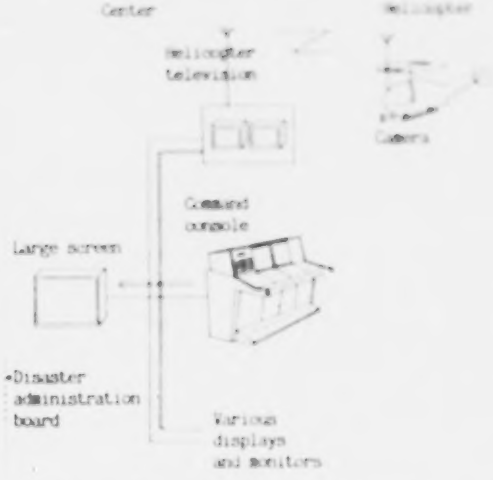


Figure 6 Configuration of tactics system

The implementation of the tactics system enables appropriate instructions to be supplied to people at the site.

Figure 1 Configuration of radio facsimile in system

The use of radio facsimile in the [illegible] shows other useful services for disaster prevention activities.

In addition, the call reception and command control equipment is backed up with spares to improve reliability. The command line to each fire station has a backup line. The software is designed so that it can be changed through system parameter adjustment.

5. FUTURE PROSPECTS

Technology advances rapidly, and it is difficult to help in unified system design schemes. It will soon become necessary to redesign the system to use better methods for vehicle location, vehicle navigation, and mobile command systems.

This system is also expected to offer integrated civil services including fire protection emergency information services and first aid and public guidance services.

6. CONCLUSION

The design of the fire protection emergency information systems have been discussed. This design was implemented in an urban area. The environment for fire protection emergency information systems is expected to change considerably in response to advances in technology.

As systems engineers, we are trying to provide better services and minimize accidents and requests from users of this system.

I hope this paper will be of help to people who design fire protection emergency information systems. We will continue our system engineering efforts to improve customer services.

LOW COST MEANS FOR GLOBAL DATA TRANSFER FOR SOPHISTICATED TECHNICAL TASKS

A D S N Kularatna
Arthur C Clarke Centre
Katubedde, Sri Lanka

and

Martin J Allard
Mallard Concepts Ltd
Devon, United Kingdom

ABSTRACT

The paper highlights the experiences gained by a research and development team in a developing country, working in collaboration with British engineers using self-contained electronic mailboxes. Like many other developing countries, Sri Lanka does not have a public data network and the mailboxes described in the article is an extremely useful way for data communication purposes using dial-up connections through the low grade, unreliable telephone lines. The paper highlights the details of an exercise of a Printed Circuit Board (PCB) layout transfer and the mailbox system.

INTRODUCTION AND HISTORY

Like many other developing countries, Sri Lanka does not have a public data network yet, even though the plans are underway to establish such data networks in the near future. For various requirements the users were demanded to device their own ways to establish data connections within the last decade using either dial-up connections or dedicated circuits. Most of such usages were for business purposes etc and any significant use of such data connections over international circuits for research and development activities were a rare occasion.

Almost at the inception of the Arthur C. Clarke Centre for Modern Technologies (ACCMT) - a government funded research and development centre established in honour of godfather of satellite communications, Dr. Arthur C. Clarke - was assisted by the Division of Communication Development of UNESCO. In the process the electronic mailbox described in the paper was introduced and installed at the Centre, where international direct dialling circuits were available. The project by UNESCO was to assist developing country institutions in establishing data communication links for document transfer purposes with a view to compare the mailboxes and similar devices with more expensive means such as telexes or faxes. Through the mailboxes the R&D team at the ACC was communicating with British collaborators and UNESCO officers etc regarding the daily progress of their R&D activities.

As the R&D work was very progressive at the ACC the usage of CAD packages etc were demanded for the tasks of PCB development etc. However the complex PCBs demanded for various projects particularly for the microprocessor based Data loggers designed for power line quality monitoring purposes were difficult to fabricate in Sri Lanka. At the same time deadlines demanded by the project sponsors - Lanka Electricity Company (Private) limited forced the design team to look for fabrication facilities who could complete the tasks in several days time. The PCB layout - a double sided, through hole type, which was to accommodate about five (5) VLSIs and fifteen (15) standard TTL / CMOS type chips as shown in figure 1 was created using a PC based layout package, Easy-PC, described in its User Manual in reference 1.

The layout was creating a schematic file with over 30 K bytes of data. At this stage the British collaborators were having access and the experience with a PCB fabrication facility and were convinced that the PCB could be available before the deadline if the layout was available in its final form in UK. The mailbox described in the article being capable of binary file transfer, an experiment was conducted to evaluate the success of using such inexpensive means for sophisticated tasks.

MAILBOX USED

The mailbox shown in photograph of figure 2 was designed to serve two independent purposes. It is an error-proof high speed duplex data link between a computer and a remote terminal or second computer, and is also an electronic mail service with off-line message entry and automatic delivery.

When used as a Modem, the unit provides auto-dial and auto-answer, and the protocol which it uses offers error-free communications even over bad lines. The only trade-off is that the speed falls if the line is of poor quality.

Conventional electronic mail systems depend upon the use of a central computer, accessed by simple dumb terminals over an unprotected asynchronous link. This system requires no central computer and the messages are delivered directly from one mailbox to another, where they are held in battery-backed semiconductor memory.

A flashing led indicates that mail has been received. There is never any need to call a central bureau to find out whether any messages

319

have been left: the recipient has the message there in his mailbox and the sender has a reliable acknowledgement of the delivery.

Furthermore a message is not marked as 'delivered' in the sender's unit until every character has been checked and confirmed correct in the destination mailbox. Several levels of error recovery procedures, acknowledgements and interlocks are used to make the system very reliable.

The sender and recipient of mail both interact with their mailboxes off-line (figure 3). Actual transmission of the mail is normally performed fully automatically at night. For a typical short message the telephone call lasts only a few seconds, which at cheap rate means that the cost is less than that of a second class letter (in British Isles). The total capacity available for storage of message text is 52 Kbyte.

All telephone lines are liable to be noisy, and so all simple Modem standards are prone to errors which make terminal use frustrating and file transfer difficult, without running special protocol software in the host computer at each end of a link. Electronic mail is most useful and habit-forming facility to have access to, but it usually depends upon the use of either a central computer or compatible hardware and software at each node.

Physically, the system consists of a single Printed Circuit Board which contains a microprocessor with 64 Kbytes of memory, a battery-backed real-time clock and a 1200 baud Modem. External connections of the unit are mains input, telephone line and an asynchronous RS232 line to which either a terminal or a computer can be connected.

Several methods of originating and answering telephone connections, either automatically or manually are provided. Whenever the mailbox is on-line to another such system there is a duplex link open between the two terminal connections which is independent of the mail system. When off-line, the terminal line can be used to enter messages (or even binary files) for later delivery to another node, and to read incoming electronic mail.

Each mailbox is given a unique name, and the mail delivery system is based on these names rather than on telephone numbers. Three levels of delivery service are provided. First class mail is sent at once, second class mail is sent overnight and third class mail is sent only when the opportunity arises.

Whenever two units are connected, they exchange names and each scans its list of mail to see if it has anything to send to the other one. Any opportunity to transmit mail is always taken advantage of.

The mailbox uses a 1200 baud half-duplex standard (CCITT V23) with provision for fast direction switching. The HDLC link-level protocol chosen, with a variable packet size of upto 64 bytes.

The half-duplex system requires an extra 32 bytes in order to transmit 64 bytes of user data. This may seem a lot, but it includes the time spent in switching line directions, locking up the receiver clocks and sending the necessary error detection and link house keeping information. The return for this reduction in data rate to two-thirds of the line bit rate, one is guaranteed that the data will be received with an error rate which is independent of line quality and which is so low as to be for all practical purposes non-existent. Standard XON / XOFF characters are used, which are recognized already by most operating systems. Separate provision is made in both real-time link and the mail system for the transparent transmission of arbitrary 8 bit binary files. Under all normal circumstances there is no detectable limitation on the speed at which a terminal user is allowed to type in to the system. Figure 3 shows the mailbox functional diagram. For usage information and detailed technical information on the mailbox reference 1, 2 and 3 are suggested.

The latest versions of the mailbox ME43 and ME44 use an integral software package 'MailMan'. The program is for use with IBM PCs and compatibles, and allows the users to organize mail messages sent and received by the mailbox. All day-to-day management of the mailbox is handled by the MailMan software. Although the software is not copy protected, each copy of MailMan is specifically configured for use on a single Mallard Mailbox.

USE OF A DATA COMPRESSION TECHNIQUE TO SAVE TELEPHONE BILLS

In the particular data transfer experiment in order to save the IDD telephone bills a standard data compression technique based on Lempel-Ziv-Huffmann algorithm was utilized. This helped reducing number of bytes be transferred from over 30 Kbytes to less than 18 Kbytes. This made a very reasonable saving on the telephone bill, and only approximately 6.5 minutes of connection time was used. For the details of the compression technique one may refer to reference 4.

REMOTE END ACTIVITIES

At the remote end UK, the graphics layout was transferred on to a similar mailbox (named MEA) from the mailbox at ACCMT (named ACCENT) totally error free. Decompression of the graphics layout recreated the total PCB layout on the remote PCs. The final error free PCB layout was later transferred to a PCB fabrication facility where the PCBs were to be fabricated. At the remote end the received PCB layout was checked (for reconfirmation purposes) using the same PCB layout package used by the Sri Lankan team. Fabricated PCBs were received in Sri Lanka through a courier service well before the deadline demanded.

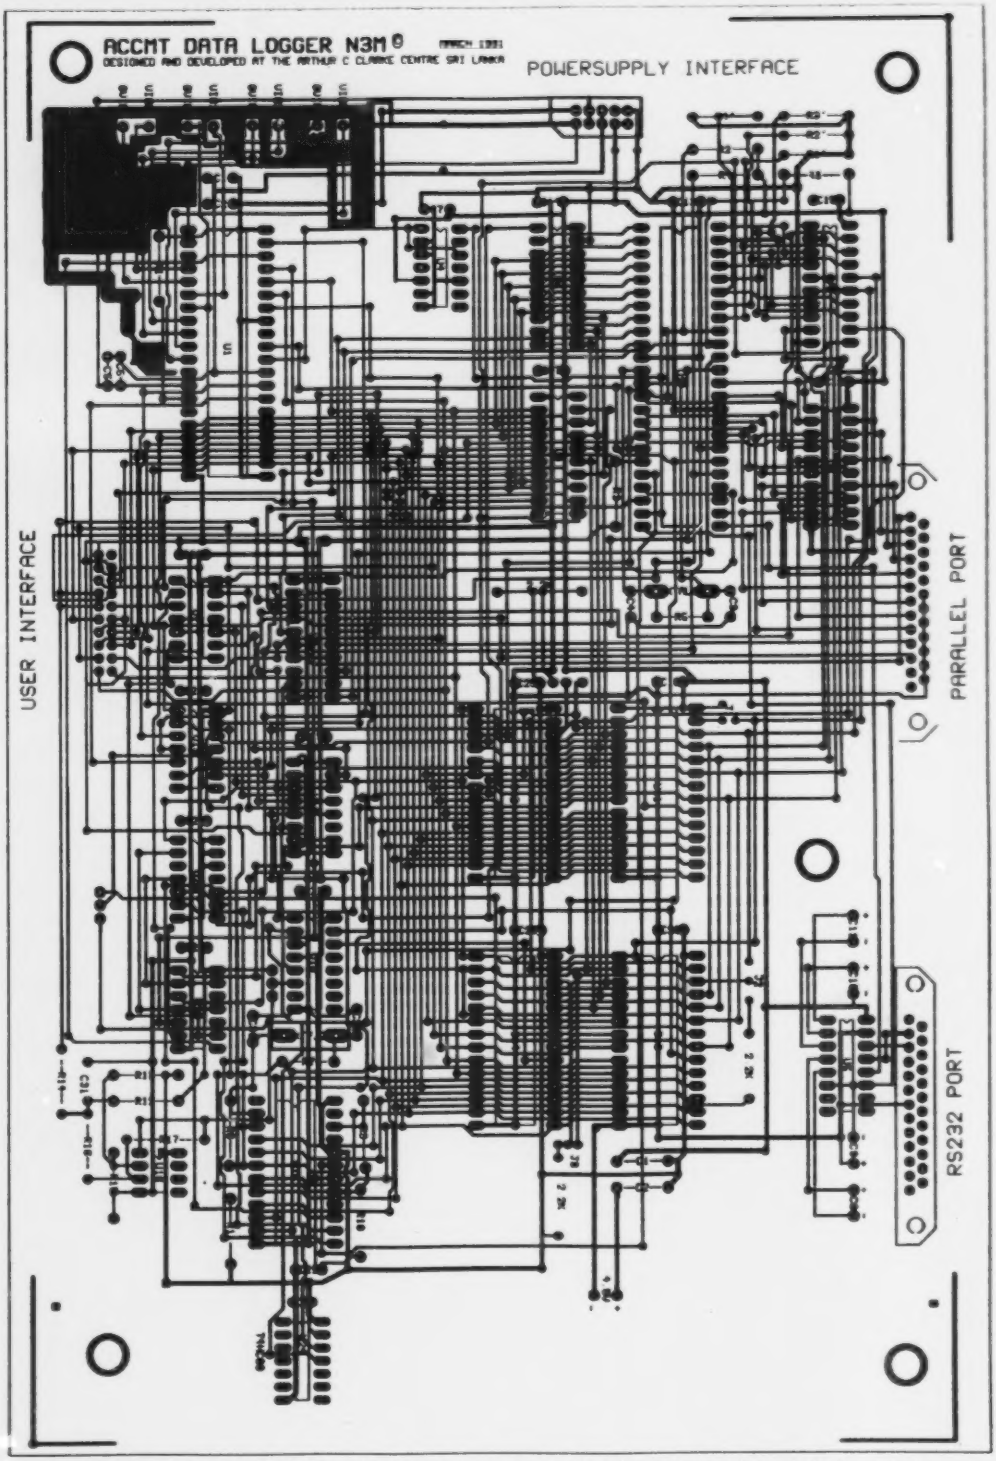

FIGURE 1 - The Printed Circuit Board layout - a double sided, through hole version which was transferred via mailbox experiment. Note that the diagram shows both sides of the PCB together.

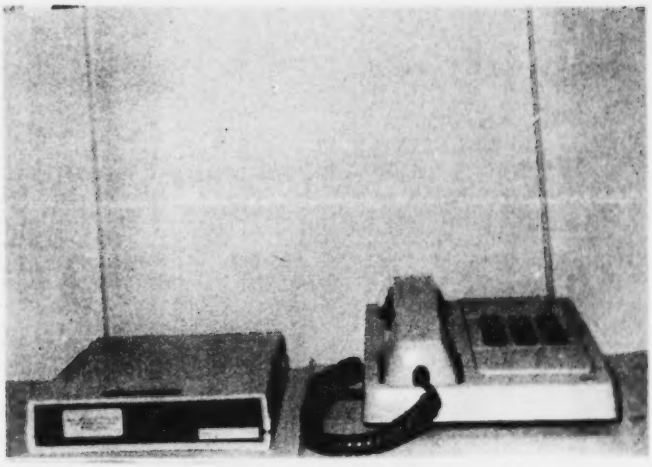

FIGURE 2 - The Mailbox Used

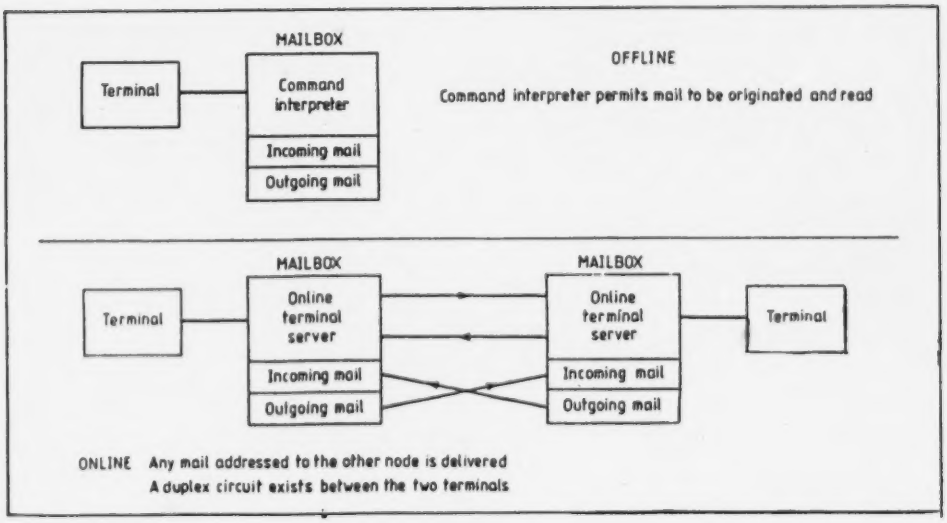

FIGURE 3 - Mailbox functional diagram. Outgoing messages are entered into the mailbox from a terminal or computer through an RS232 link. Software in the mailbox makes entering the message very simple. One may send the message immediately or leave it to the mailbox to send it later on, when calls are at cheap rate. Using 'third-class', the sending mailbox only sends its message when the destination unit makes contact - which is even cheaper.

EXTENDING THE USE OF MAILBOXES FOR OTHER SOPHISTICATED TECHNICAL TASKS

The design of the mailbox allows the binary or ASCII file transfer totally error free and could be used for sophisticated tasks where an average fax, telex or even a standard and popular e-mail connections do not permit. The approach used in the particular experiment was to transfer the graphics layout / binary file on to an identical mailbox and from which the files could be manipulated again with the identical PC packages for further engineering tasks be carried out. The experience well proves that the graphic files created by common packages such as Auto CAD etc are easily transferable (internationally) using the mailboxes. The other advantage is that the unauthorized access to the data is not easy, due to inherent security features on the mailbox. The telephone company charges involved are only the call charges and does not demand any subscription charges for gateway access or network services.

SUMMARY

The experience gained by the developing country R&D group and the British engineers team indicated that the self-contained mailboxes described in the article can be easily used as a cost effective alternative to the use of public data networks or leased lines, for graphic file transfers and similar tasks.

ACKNOWLEDGEMENT

Authors gratefully acknowledge the efforts of the Research Engineers of the ACC - Parakum Fernando, Nihal Samaraweera and Manjula Ellepola - design team members of the Data Logger project for their kind assistance.

Our sincere gratitude is to Dr. Carlos Arnaldo of UNESCO who assisted in the funds needed for the fabrication of PCBs in a UK facility.

Government Information Services and Telecommunication Technology in the Pacific Islands: Using the Iowa City Information Services Model

Mark A. Tolstedt
University of Wisconsin-Stevens Point

Ronnie Bankston
University of Northern Iowa

This study is concerned with how governments use information technologies, such as the telephone and television, to provide information to its citizens. After providing a case study of the Iowa City Government's Information Service, this study, using Guam as an example, speculates that an economical and technologically realistic approach for Pacific Islands governments' dissemination of information is readily available for adaptation.

> "With the availability of greatly expanded electronic communication facilities, better access with less delegation of authority could be provided. With a more informed public and with the possibility of automatic opinion sampling or voting, a much greater degree of direct participation at all levels of government would be available... It could lead to great social understanding and greater access to and transfer of information while improving the opportunities for both freedom and privacy!"
>
> J.L. Holt, "Cheap Communications," The Futurist, 1969

Over the past decade and a half, information technologies have undergone an explosive growth and rapid diffusion in numerous Third World and Developing Countries around the world, including the Pacific Islands. Although the adoption of many inventions and innovations varies depending on systematic, contextual, and aggregate reasons, television and telephone technologies are usually among the first adopted and diffused. Information dissemination through technological means is usually seen as a legitimator or motivator, a political "lightning rod," an accelerator of interaction, an organizer and maintainer, an institutional catalyst, and as a means to improve the physical qualities of life.

Historically, the adoption of information technologies has evolved as the technologies have evolved; from the press to the telegraph to telephone to radio (wired and wireless) to television (broadcast and cable) to videocassette to the computer. The successes of such technological adoption for information dissemination have varied, depending on a variety of reasons, including how the term "success" is defined. Out of such concerns, the notion of "appropriate technology" evolved. Essentially, appropriate technology calls for the adoption of information technologies that are appropriate for the political, economic, and social variables present in a developing or third world country.

This study is concerned with how governments can utilize the technologies of the telephone and television to provide and disseminate information. After a review of the Iowa City Government's Information Service, which utilizes cable television and touch tone telephone technology for an interactive information system, this study suggests that implementation of such a system among Pacific Island nations would be economically and culturally appropriate.

GOVERNMENT INFORMATION CHANNEL 29

The City of Iowa City, the Iowa City Cable TV Office, and the Iowa City Broadband Telecommunications Commission are trying to marry television, telephone, and computer technologies. As a result, residents of Iowa City and Coralville, Iowa have access to an interactive video system that provides a wide range of community information cagegories. Housing information, job opportunities, community calendars, and election information are only an interactive session away.

System Development

In 1980 Drew Shaffer, a cable television specialist for the city, and several friends began to develop an interactive video system. The partnership, known as Response Television Corporation, pursued the project during the early and mid 1980's. In 1986 Shaffer met city officials to discuss the possibility of testing the system in Iowa City (1). Later that year initial tests were conducted with a minimal number of categories and screens. The system continued to operate in this experimental mode until 1989 when an interactive specialist was hired and the number of information categories increased. Since 1989 the number of information categories, screens, interactive sessions, and project staff have increased significantly.

System Design

Government Information Channel 29 is a single-user system that does not require a home decoder or keyboard. The user only needs a touch-tone telephone and a television set to interact with the system.

On the sender end, the system is tied to an Amiga 2000 computer and a software package developed by Response Television Corporation. Information is distributed from the computer to the cable system via a genlock and modulator.

1. The user turns his or her television set to cable channel 29. Users with cable-ready sets will tune in channel 30.

2. The user will call 356-5478, which is the information services phone number.

3. Hardware developed by Response Television Corporation decodes the phone signal and directs the user through the software.

4. The user will watch the television screen for directions. Information can be requested by pushing designated telephone buttons.

5. The computer will generate the desired category and screen, which is distributed on the cable system to the user and anyone else that is viewing the channel.

6. An interactive session, which is recorded by a computer, can last three minutes. The session's backtime, which is the amount of time left in the session, will be displayed at the top of the television screen.

7. A three-minute session will be terminated by a computer generated voice that says, "Bye, and thanks for your interactive use."

Information Categories

The system started with only four or five information categories and approximately fifty screens. This limited menu allowed users to gain access to city council agendas, commission meeting agendas, and information about access programming (2). By the fall of 1990 the system had expanded to over twenty-five information categories (3). Users could now gain access to information about taxes, elections, missing children, jobs, recycling, bus routes, jokes, and cartoons.

As system awareness and usage

increased new information categories emerged and existing categories were allocated more screens. In the last year the system has expanded at an unbelievable rate. Today there are over seventy categories available to users.

73. SAFE SEX- PHONE NUMBERS FOR MORE INFORMATION

74. SIGN LANGUAGE ALPHABET

The information categories are updated continually. Categories that are time sensitive require more maintenance. For example, job categories must be updated at least once a week, while bus routes may need little or no attention for a six-month period (4).

Usage Patterns

Government Information Channel 29 is expanding very quickly. However, the pattern of usage appears to be somewhat constant over time. Viewer usage data for the week of October 6-12, 1990, indentifies the Directory, Cartoon, Zodiac, interactive poll (You Tell Us), Ivy, Fun Facts, Radar Locations, Jokes, Welcome to Iowa City, and Instructions as the top ten categories (5). Viewer usage data for the first quarter of 1991 identifies the Directory, Jokes, You Tell Us, Fun Facts, Cartoon, Zodiac, Interactive Maze, FBI Wanted Posters, Instructions, and Radar Locations as the top ten categories (6).

These usage patterns might indicate that system users are going through an experimental stage and/or prefer the entertainment categories of the system. Thus, the information obtained may not be as critical to some users as the interactive process itself. However, increased usage in the jobs, recycling, and city news categories indicates a demand for more "serious" information.

While the pattern of usage has remained somewhat constant the number of interactive sessions have grown significantly. Between January and March 1990 approximately 1500 calls were made to the system. During the same time period in 1991 system use had grown to approximately 10,000 calls (7). As of September 1991 the system was receiving between 800 and 1000 calls per week (8).

Future Plans

At the present time the system is available whenever city government programs are not being broadcast. Thus, channel 29 is used primarily for the interactive video system. However, the rapid growth of the system warrants a separate channel. This option is under consideration at the present time.

As the system continues to expand,

via a separate channel or in a shared-channel capacity, Schaffer and his staff will add and delete information categories to meet community needs, examine ways to make the system more accessible to users, and maintain localism as a primary operating principle.

The Information Services Model in the Pacific:
A Case Study of Guam

The marriage of the computer with cable television and the telephone in Iowa City has given the city government a unique opportunity to provide information to the community. The amount of such information available is limited only by the ability and desire of the city government to provide materials. Access to the information is easy to gain and convenient to the user.

Countries or cities with cable television systems in operation would be able implement the model with a relatively low capital investment. Costs would be limited primarily to the software package, computer, modulator, and gen lock hardware, an incoming telephone line, and the staff required to input and update the information materials.

Because the Pacific Islands have a high rate of urbanization, due to small, often-time mountainous land areas involved, cable television becomes an ideal distribution technology for government information. Guam provides a good example of how the information services model might be implemented.

Guam, a territory of the United States, has approximately 135,000 people for a land mass of 209 square miles (9). Approximately one-third of the land is owned by the U.S. Armed Forces and the majority of the population is concentrated in the vicinity of the capital. English is the official language, although the majority of the residents are of Chamorro, Filipino or Micronesian descent. U.S. military personnel and ex-patriots comprise the remainder of the population. The tourist trade is second only to the U.S. military in economic importance. There are some agricultural and light manufacturing industries which also contribute to the local economy as do the more than 13 banks and 7000 government employees.

Given the variations in the economy and ethnic backgrounds of the population, the methods by which the Government of Guam disseminates information become crucial if the information is to reach the intended audience. With a cable television system already operating, using the information services model would seem an appropriate dissemination technique.

Cable Television on Guam

> "The Guam Cable T.V. system is probably the most significant cultural medium on the island today... the cable phenomenon began in 1968... and now reaches to all parts of the island, including military installations. Indicative of the system's popularity, the requirement to have a specific home address for cable service has probably caused the greatest impetus to having house numbers in many villages" (10).

The Guam Cable T.V. Company has over 580 miles of cable which pass by roughly 33,000 homes; about 90% of homes in the area (11). There are over 25,000 suscribers; about 75% of the homes in the area. The system has the capacity for 35 channels and currently operates 8 television and 4 pay cable channels. The basic cable also includes 10 channels, such as CBN, Discovery, ESPN, MTV, etc. The system also has 5 originated channels for classifieds, a program guide, live legislative sessions, hotel entertainment, and news and community events (12).

The high cable penetration rate and the diverse needs of the Guamanian population provide an almost perfect "setting" for the Information Services Model. The interactive ability of the model provides the consumer the opportunity to choose from the various

information categories. The almost unlimited number of information categories could allow the Government of Guam to program information sensitive to the diverse needs of the population. Some categories might include: agricultural information, voting information, weather information, hotel entertainment, tourist information, police information, tax information, job information, church information, transportation information, U.S. government information, historical information, housing information, health information, land information, political party platforms, and so forth. The information categories could be programmed in different languages, thereby allowing for non-English reading citizens access to the materials. In short, the information services model can provide for the Government of Guam a relatively low-cost, technologically realistic method for disseminating materials to meet the information needs and desires of its citizens.

Some Concluding Remarks

The Pacific Island Nations represent one of the most diverse regions of the world in terms of politics, languages, governments, and cultures. The political entities represent various stages of dependence and independence while the economies are usually very heavily dependent upon one export commodity, tourism, and development aid. The people, languages, cultures, and requirements of those cultures are as varied as the names of the Pacific Island Nations suggest. The implementation of the Information Services Model could help the governments to meet the needs of their citizens.

Because the Information Services Model utilizes cable television for information dissemination, there needs to be a high rate of urbanization present in order for the cable system to be economically viable. Many Pacific Island Nations have urban, capital centers with operating cable systems and rural areas (sometimes separate islands 600-700 mile distant) without access to a cable television system. In such cases, cable television distribution is not economically viable. The recent trend, however, towards the deployment of fiber optics across the Pacific could render such physical distances obsolete. Indeed, some optimistic projections suggest that within the next decade, fiber optics will replace coaxial deployment completely for all telecommunication services. If this happens, the Information Services Model could provide an appropriate technological means for dissemination of government information to all portions of the country; urban and remote.

The Trend of Voice Message Services in Advanced Information Society

Kaoru Kazama and Kunitoshi Sugi
NEC Corporation
Tokyo, Japan

ABSTRACT

The information science in the modern world is changing with dizzy rapidity. For communications infrastructure, telephone networks play a major role as the core of information-oriented society.
The changing world demands more and more value-added services to be provided through telephone networks, in order to cope with user's diversifying needs, rather than the assurance of transparent communications services required for the conventional telephone networks.

This paper discusses the trend and some instances of voice message services in Japan, in particular, to infer a would-be destination of the future telephone network development.

1. INTRODUCTION

Since 1985, three new common carriers launched their operations as part of communications infrastructure, following Nippon Telephone & Telegraph Co. Ltd. (NTT) who had been monopolizing the role of Japan's communications infrastructure for telephone services.

Telephone networks are basically and critically required to provide the integrity of speech. For this reason, conventional telephone networks are operated basically for providing transparent communications services.
As the information-oriented society advances, however, telephone networks are being required to provide audio database service and other value-added services to overcome the time-lag in communications.

2. THE TREND OF VOICE PROCESSING EQUIPMENT TECHNOLOGIES

Voice processing equipment is an indispensable tool for the implementation of value-added services through telephone networks, since the communication media is basically human voice.
The voice processing equipment consists of "Audio Database Equipment" primarily for voice mail services and "Voice Response Equipment" for interactive communications with telephone sets as computer terminals.

NEC marketed its VS-series voice processing equipment in 1983, featuring easy connection to existing telephone networks, and is capable of implementing various services by the host computer control.
The authors will introduce the trend of Japan's voice processing equipment technologies on the basis of the preceding voice processing equipment.

2.1 VOICE ENCODING AND DECODING TECHNOLOGIES

Japan's voice processing equipment commonly employs Adaptive Differential Pulse Code Modulation (ADPCM) to obtain higher quality of sound.
The current bit compression widely ranges from 8 Kbps to 32 Kbps.
With the recent technological development, the technology for 8 Kbps has already been proven for laboratory use.
Most manufactures, however, employ a bit compression of 32 Kbps, since they give more weight on the sound quality.
The use of optical disks is being implemented by some manufacturers, although hard disks are commonly used as media for the memory of compressed voice.

2.2 PROVISIONS FOR VOICE INPUT

The use of voice processing equipment is required to give an instruction to the equipment for a service to be provided.
Normally, the user's instruction is given by sending telephone push-button dialing signals, so that nearly 100% correct recognition rate can be attained.
Unlike the United States, only 30 percent of the total telephone subscribers in Japan use push-button dialing telephone sets and the remaining 70 percent use conventional rotary dialing telephone sets.

Since Japan's public telephone networks do not have a function for the direct transmission of rotary dial pulse signals, signal conversion equipment capable of converting a rotary dial signal into a push-button dial signal is required in order for the voice processing equipment of push-button dial signaling system to receive rotary dial signaling instructions.

Many types of multi-function telephone sets now available in market use the rotary dial pulse for call origination, and transmit the push-button dial signal on and after the call setup.

It is considered that in Japan the availability of such technologies allowing the equipment to receive the rotary dial signaling

instruction would be a key factor to the successful implementation of various value-added services with the voice processing equipment.
The preceding signal conversion equipment for changing the rotary dial pulse signal into the push-button dial signal is already available in Japanese market, but not ready yet for general use because of some problems existing in the recognition capability.

In the long run, it is suspected that the natural human voice will be used for the input by voice recognition, in place of the use of a telephone function. (sending of push-button dial signal or rotary dial pulse signal)

It is conceived in the short run that the input of push-button dial signals will co-exist with that by the voice recognition for the time being. For voice articulation, it is expected that the intensive packets of superior technologies, such as single-sound synthesis and syllabling technique, will be put to practical use.

3. THE TREND OF VOICE MESSAGE SERVICES

In the United States, voice mail services are widely utilized among business firms as a means of overcoming the time-lag.
A type of information services, known as the "900s" information service, is generally accepted by many users as a voice message service.

In Japan, the development of the voice response service that communicates interactively with computers preceded that of the voice mail service, because no time-lags are geographically applicable in Japan.

NTT launched so-called "Dial Q" service, one of NTT's numerous services, for allowing contractual information providers to send required information to their customers via telecom circuits (telephone, videotex, etc.) and for collecting information charges on behalf of the information providers. This service is equivalent to one of the "900s" services in the United States. This triggered the rapid spread of voice mail service in Japan and its marketability indicates a promising expansion.

The following figures shows how fast "Dial Q" service has been developed in Japan:

Period	Number of programs put on mass media	Sales
March 1990	166 programs	$1 million/month
July 1990	600 programs	$10 million/month
March 1991	10,700 programs	$100million/month

In the not-distant future, a composite service, a combination of "voice processing equipment" with other media (e.g. facsimile mail and electronic mail), will be rapidly developed for practical use.

4. SOME APPLICATIONS OF VOICE MESSAGE SERVICES

Introduced below are some applications of the voice message service in Japan.

4.1 VOICE MAIL SERVICE WITH PAGER FUNCTION

This service is provided in the following way; by recording a message on the audio database equipment and giving the pager number of a called party, the audio database equipment will automatically call up the pager so that the owner of the called pager can call up the audio database equipment to receive the message.

Because the message is conveyed directly by human voice in place of conventional messaging in the form of a memo, there will be no room for making an error in message transmission, in addition to the merit in additional messaging effect by a specific tone of voice; for instance, a critical situation can be conveyed with such a tone of voice.

This service is effectively utilized among business firms; for instance, when communicating with sales persons working outside or when communicating with each other among sales persons.
Some companies in Japan are doing their business by providing this service.

A system configuration for the voice mail service with a pager is shown in Figure 1.

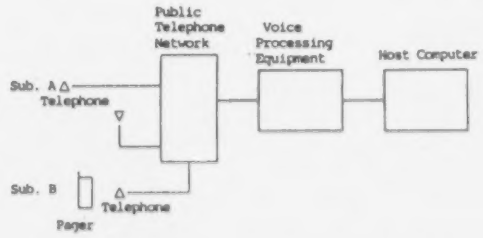

Figure 1 SYSTEM CONFIGURATION FOR VOICE MAIL SERVICE WITH A PAGER

4.2 SEAT RESERVATION SERVICE

This is a service to be provided for seat reservation by telephone, as is seen in railroad, airline, and long-distance bus services.
In either service, a telephone set is connected via a public telephone network to a host computer so that the telephone set can be operated as an interactive computer terminal.

An instruction is given to the host computer by inputting various conditions (the date of boarding, from where to where, the number of persons, etc.) to make seat reservation.
This service is also provided widely in Japan by railroad companies, airline companies, and various mail-order firms.

Japanese major railroad companies and airline companies have installed the voice response equipment in cities where host computers are located for seat reservation control.

A sufficient number of voice response equipment are installed throughout packet networks within Japan so that the assessment of larger access charges to remote area users can be avoided. Thus, the seat reservation service will reduce the labor of users, with the aid of host computers provided for seat reservation control.
An example of typical system configuration for this service is shown in Figure 2.

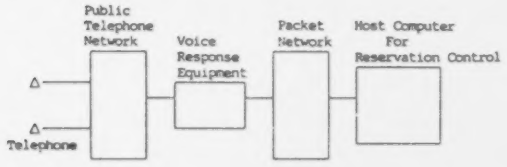

Figure 2 SYSTEM CONFIGURATION FOR SEAT RESERVATION SERVICE

4.3 INFORMATION PROVIDING SYSTEM USING MULTIMEDIA

"Dial Q" service (may be one of the "900s" services in Japanese version) will provide various types of services; most of them are services for providing various voice information recorded in the audio database equipment on a charge basis.

That is, the service providers operate their business by recording user information in the audio database equipment attached to public telephone networks, while allowing users to utilize their own audio database equipment for recording the user's information to be provided.

Recently, a multimedia-type information providing service has become available in Japan, which provides not only voice information, but also video information with the aid of a facsimile database equipment.

Figure 3 shows a system configuration for multimedia-type information providing service using a facsimile database equipment.

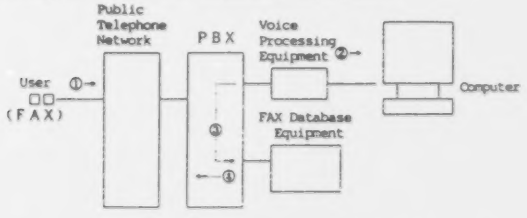

Figure 3 SYSTEM CONFIGURATION FOR MULTIMEDIA-TYPE INFORMATION PROVIDING SERVICE

(2) Required information is selected according to push-button signal.

(3) The voice processing equipment will transfer the information to FAX database equipment by making use of PBX extension line transfer function.

(4) FAX information in the FAX database equipment is sent out.

5. TELEPHONE NETWORKS - WHAT IT SHOULD BE IN THE FUTURE?

Telephone was invented by Graham Bell about 100 years ago and the times of manual switching system continued for some time since then. With the emergence of automatic switching system, so-called the information-oriented society has been drastically matured as is seen today.

On the other hand, however, the authors are of the opinion that the sophistication of modern communications has brought about dehumanization or a lack of human nature. We call a name of the other party in our conversation or in our letters.
Although a call was set up by calling names of a calling party and a called party during the period of manual switching, the automatic switching system sets up a call using emotionless and inorganic numbers, irrespective of our liking.

The authors feel as if we are in the midst of Charlie Chaplin's Modern Times, in a sense, satirizing the fact the human being was dominated by machine.
However, the authors consider that the dehumanization can be recovered to a remarkable extent by introducing the preceding voice processing equipment into existing communications infrastracture, along with the on-going development of technologies.

- "Personal" addressing in voice recognition technology:
  Implementation of communications approach by addressing names of calling and called parties, not by using inorganic numbers.

- Effective use of audio database equipment:
  Implementation of automatic message recording service when the called party is busy or absent to eliminate a bother to reattempt a call.

- Incorporation of multimedia:
  Implementation of optional services in which the user can select a preferred terminal device so that the user is not bound to use any device determined by machine.

Although these services are often provided by secretaries in most business firms, general public will also be privileged to receive even services after the implementation of

new communications infrastructure. Again, the authors wish to stress on that existing telephone networks should be eventually oriented towards the recovery from dehumanization with the help of further technological development, with the result that the user would feel a sort of the warmth out of humanized communications infrastructure.

6. CLOSING REMARK

NEC is making every effort in the research and development in various fields, including voice recognition technology, single-sound synthesis technology, and information management technology, to keep abreast with the advancing information-oriented society.

A PRIMER ON TELECOMMUNICATIONS STRATEGIES FOR THE DELIVERY OF DISTANCE LEARNING

F. Barry Brown, EdD
Professor
Department of Communications, Continuing, and Vocational Education
College of Education
University of Saskatchewan
Saskatoon, Saskatchewan
Canada S7N 0W0

ABSTRACT

A continuum of delivery strategies for distance learning is developed to provide an historical perspective on present and emerging developments in telecommunications delivery of training and learning programs. Strategies from early face-to-face, print-serviced modes to present-day compressed video conferencing and future multimedia modes are reviewed from an introductory standpoint.

Introduction

Technologies for the delivery of learning are not novel, although one is left with that impression considering the pace at which telecommunications technology is developing. An unprecedented number of strategies for delivery of learning to the distance student are available to today's educators. The scope, diversity, and rate of change make selection of appropriate delivery mechanisms difficult and risky. Yet these decisions must be made and a stake driven if education and training are to remain abreast of the need.

A significant segment of change is occurring in video technology. The "video revolution", now of landslide proportions and gaining momentum, is due largely to advances in delivery technology. Television has been the mass medium of choice for over four decades, providing powerful life-shaping messages in areas of entertainment, news, and lifestyle. Video coupled with the computer and delivered via new digital technologies is putting the learner and the instructional developer in the "digital driver's seat". The union of computer and television with the new technologies of digital storage and delivery produce a technology called "multimedia". This technology gives added substance to the concept of television as a "universal medium" which has prevailed for forty years. Compressed digital video (CDV) is the glue which ties together diverse technologies by providing exceptionally cost-effective communication when bandwidth hungry analog transmission is reduced to narrow bandwidth by digital transmission. A dramatic illustration is the 6000 to 1 compression which occurs when a video image for a freeze-frame videophone is compressed from a full motion transmission rate of 90 megabits per second (Mbps) to 19.2 kilobits per second, allowing transmission on standard telephone lines (90,000,000 bps to 19,200 bps).

In its time the book was as novel and revolutionary as today's advanced multimedia delivery systems and held no less promise. Increased communication and interaction between the teacher and the student has been a driving force underlying development of every technology supporting the goal of learning at a distance. Existing delivery technologies have enjoyed varying levels of success in addressing the needs of the distance learner. Emerging technologies, particularly those involving a telecommunications component, have the potential to catapult distance learning to the forefront of the educational process. The client pool for non-traditional delivery of learning far exceeds the number of students now enrolled in traditional institution-based programs. These new technologies hold much promise as a means to attack the enormous task of education, training, and retraining facing the world as we hurtle through the few years remaining before being thrust into the twenty-first century.

The see-saw of the information and technology explosions throughout the nineteenth century has alternately created the need for and solution to the scope and level of education and training required to support the society of the time. To establish a perspective on telecommunications strategies for delivering distance learning, one must have a feeling for that which has gone before. The history of bringing learning to the student is a fascinating and integral part of present day advances in telecommunications delivery. The goal of this paper is to trace the evolution of distance learning delivery modes from the earliest person-to-person, local educational extension programming to present day telecommunications developments with global capability.

Distance learning is defined as a process of instruction characterized by separation of the

learner from the source of the instruction. In this process learning is facilitated by providing the learner with links to the originating site for transfer of information and for interaction with the teacher. The quality and capacity of links to the learner have enjoyed a constant state of growth, from the first correspondence courses in the late 1800s dependent on the mail service for interaction, to present day full motion interactive television instruction via satellite. Interaction with the remote learner has moved from sporadic, impersonal, delayed communication to real-time personalized dialogue with the instructor. More than a century of development has improved communication modes linking the learner with the originating site. New modes have not directly replaced the old but have consistently added another dimension. The importance of print and mail service to distance learning remains high, and new telecommunications technologies have improved access and interaction.

Strategies for delivery of distance learning by telecommunications cannot be considered in isolation from the preceding modes of delivery. Present day distance learning practice is a continuum from print to multimedia and mail service to satellite service. New strategies for delivery and interaction will not instantly replace serviceable existing modes. Rather, the old and the new must form an amalgam providing the best possible situation for the distance learner. Therefore, in the zeal to adopt the new, one must never lose sight of past and present methods. The increment results when the new is integrated with the old to take full advantage of the added telecommunications dimension. Cost effectiveness is a factor of distance learning that is best served by evolution rather than by revolution.

Until the mid-1800s word of mouth was the predominant mode for distance learning, and the instructor physically attended the instructional site. This mode remains predominant in many parts of the world today. Once print became established in the form of books, manuals, and newspapers, instruction at a distance was enhanced by learner access to a multitude of print-based information. Paper-based print formed the backbone of instruction at a distance for the past century and will remain a major information carrier well into the next century.

Delivery Continuum

History of distance learning delivery modes and devices of delivery in roughly chronological order would include: face - to- face - print - mail service - telephone - radio - audio tape - broadcast television - video tape - audio teleconferencing - cable television - videotex - telewriter - computer assisted learning - audiographics - computer conferencing - satellite delivery - facsimile - video conferencing - video disc - CD-ROM - business television - compressed video - multimedia. Figure 1 provides a graphic representation of the delivery continuum.

Passive/Interactive Modes

Media devices used to deliver the information component for distance learning fall into two basic configurations: passive devices (one-way), which do not provide interaction with the instructor, and interactive devices (two-way) that permit direct interaction. Interaction and feedback are judged to be essential components of the learning process for all except the literate, mature, and motivated learner. Telecommunications devices used in "teleconferencing" mode are part of an "interactive technology" linking learners, often in multiple locations, by two-way communication. Whether as an inherent component of an "interactive" device or as an adjunct to a "passive" device, telecommunications can make the difference for the independent learner. Figures 2 and 3 illustrate some of the passive and interactive media.

Research points out that learning supported by the emerging interactive technologies is equally as effective as traditional methods. A beneficial aspect of new technologies for delivery of learning is the capacity of the new digital technologies for elimination of the "batch" aspect of traditional and distant learning by allowing the learner to interact on an "asynchronous" basis (not in real-time but at a convenient time) with the teacher and/or with the content base. Telecommunications strategies for reaching and interacting with the learner demonstrate potential for establishing the 90s as a "decade of the independent learner".

Face-to-Face: This is the longest standing distance learning mode, with instructor and instructional materials travelling from the institution to the learner. Attempts are made to re-create institutional settings at the learning site. This mode, usually not cost-effective, is characterized by a high degree of interaction and low availability of resources. Instructors travel varying distances, in varying conditions, and by almost every conveyance imaginable, as illustrated by Figure 4.

Print: Gutenberg's invention of the printed page enabled the distance learner. Correspondence courses, books, manuals, periodicals, and newspapers remain today as a major mode for distance learning. The book allows the learner true independence, with access any time, anywhere, and in any sequence. Print is cost-effective and rich in digital and iconic information. A vast organized body of print resources exist. To be successful, print, as a

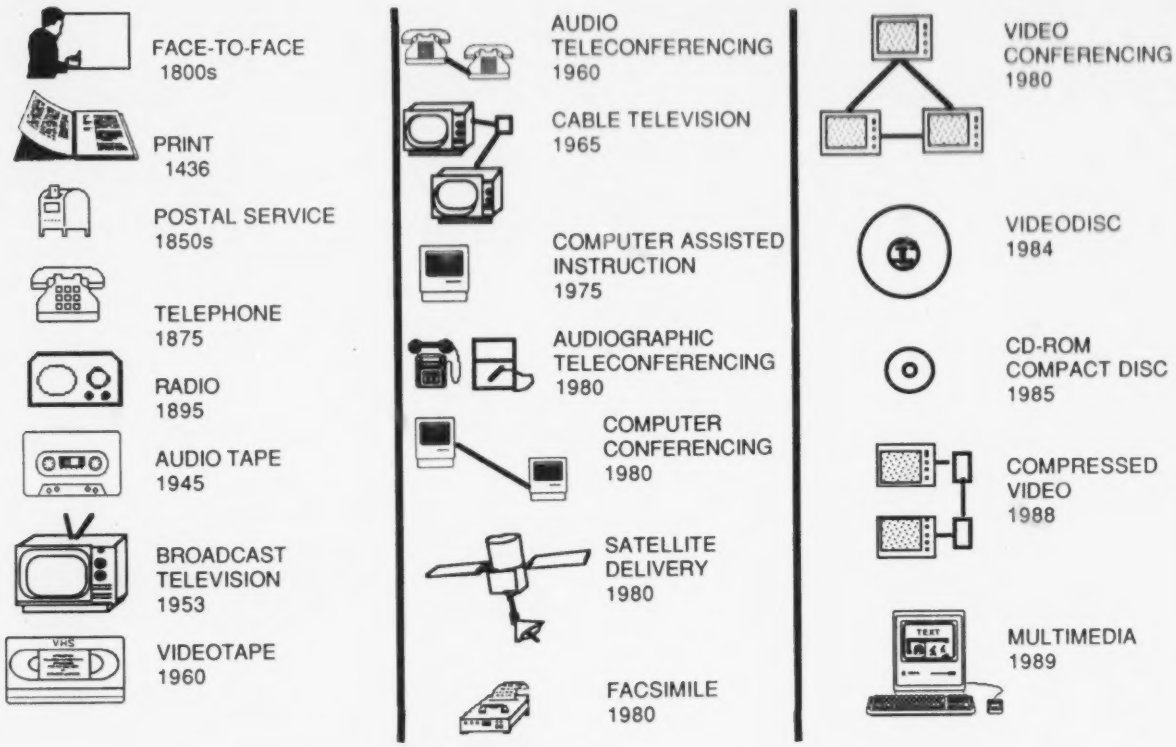

Figure 1
A perspective on delivery modes for distance learning arranged in chronological order.

Figure 2
Passive devices for delivery of programming to distance learners.

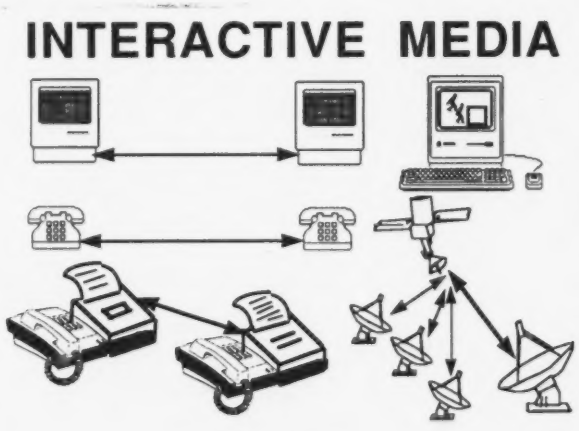

Figure 3
Interactive devices for delivery of programming to distance learners.

distance learning mode, relies upon a motivated learner with a basic level of literacy. It is cost-effective for small or large client pools, but instructional effectiveness my be reduced due to low or delayed feedback to the learner. Figure 5 outlines the various configurations associated with print and the usual forms of interaction.

Postal Service: A developed and reliable mail service continues to provide feedback as an interactive link between the learner and the instructional site. Interaction is delayed (asynchronous) and often cumbersome and inadequate. In situations where the remote learner does not have access to telecommunications the postal service is often

the only interactive link with the instructor. One-way instruction delivered by broadcast or satellite television often relies on the mail to provide interaction with the student. Mail service may provide both delivery of instructional materials and interaction with the student when learning is based on audio tape, video tape, or computer disc. Postal service is one of the most cost effective methods to deliver resources to the learner and receive feedback from the learner. Quality, consistency, and cost of interaction by mail depend upon resources available at the originating site.

Telephone: Bell's invention of the telephone made possible the first real-time (synchronous) interaction between the teacher and the distance learner. The telephone is truly a ubiquitous telecommunications device, a universal network in which one has a reasonable expectation that anywhere one calls in the world the telephone will be answered. Initially the telephone network was used to make it possible for remote learners to call the instructor and receive individual help with instructional problems. Audio teleconferencing, using a conference bridge, enabled many individuals to be networked in real time for instruction and business meetings. Some forms of video teleconferencing make use of the telephone network to transmit interactive video and audio for instruction and business applications. Recent innovations in video compression assure that the telephone network will remain a viable option for delivery of interactive learning. Digital technology and fiber optic transmission inject new potential into the telephone network

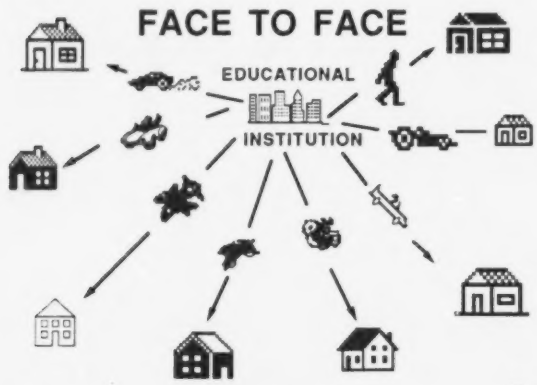

Figure 4
Face-to-face mode of delivery was the only channel available to early distance educators.

as a component of future distance learning and communications systems. The telephone network provides high interaction at low cost, and is effective for sparse, widely separated learner populations.

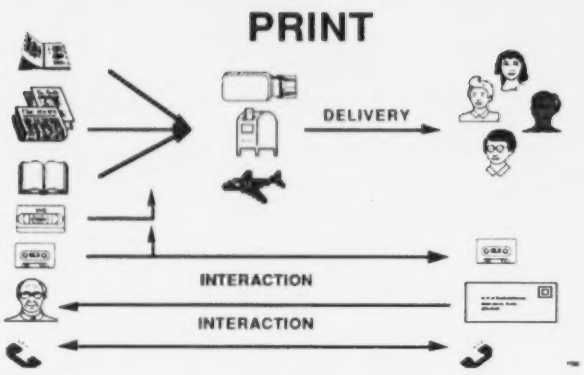

Figure 5
Invention of the printing press made it possible for widespread independent learning.

Radio: Marconi's invention of wireless communication enabled educators to provide learning to remote learners not reached by telephone and the postal service. For a number of years, schools of the air and school radio broadcasts provided learners with direct instruction and instructional enrichment. One-way audio instruction was cost-effective in that large numbers were reached, receiver cost was within reach of everyone, and cost of production was relatively low. It required an infrastructure to provide feedback and print related support materials and was instructionally effective when all components were in place because it provided motivation for the independent learner and did not require the same degree of literacy as print modes.

Audio Tape: Audio tape, particularly in cassette format, has enjoyed a long association with the distance learner as a medium of instruction and as an integral component of distance education courses. It is an effective learning medium due to portability, ease of review, potential for personalization, large body of readily available material, rapid low cost production of new material, inexpensive replay/record machines, and low cost of cassette tapes.

Broadcast Television: Broadcast television, in off-air mode, was the first medium to bring cost-effective, information rich, aural and visual information into the home. A visual channel greatly expanded the quality of communication beyond that which had been associated with telephone and radio as a delivery mode for distance learning applications Television earned the reputation of being a "universal medium" incorporating beneficial aspects of other media and is often described as "reality thirty times a second". The major drawback to broadcast television as an ideal medium for instruction was its passive one-way transmission

which relied on other media such as telephone or mail for interaction. Second, third, and fourth generation developments in television (cable, satellite, and multimedia) have overcome this limitation. Television has maintained its position as a "universal" medium by being incorporated into the multitude of modes now delivering programming for distance learning. The information rich audiovisual nature of television enhances its ability to transfer knowledge and abstractions to learners who possess minimum levels of visual and print literacy. Cost of production, inflexible schedules, lead time, technical expertise, security, and production expertise limit use of broadcast mode television as a distance learning medium. Later developments in television have eliminated some impediments, but cost and requirement for quality of production continue to limit its widespread use in distance learning. Figure 6 shows the possibilities for broadcast, cable, and satellite distribution of distance learning materials.

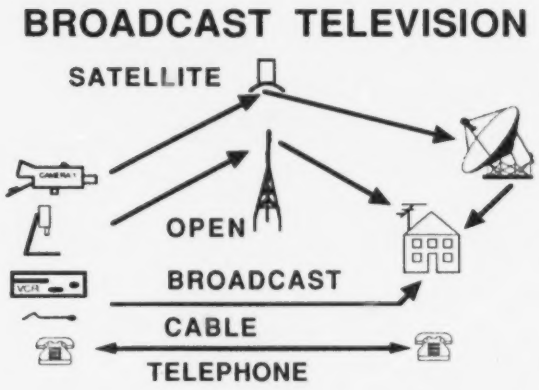

Figure 6
Broadcast, cable, and satellite television deliver full motion, color, high quality television for education and training.

Video Tape: This medium possesses the beneficial qualities of broadcast television and eliminates some of the disadvantages. Video tape is a flexible medium because the learner can use it at any time, it integrates easily with other media, has a large program capacity, low cost recording medium, and low cost replay equipment.

Audio Teleconferencing: This refers to use of the telephone on the Public Switched Telephone Network (PSTN) to enable three or more people in two or more locations to share a common discussion. The simplest teleconference uses a speaker-phone at each of two locations, enabling individuals at both locations to carry on a discussion with each other. When a telephone bridge is used a discussion between three or more telephones can be carried out simultaneously. The modern electronic telephone conference bridge permits automatic dialing of all conference participants, allows individuals to call into the conference, announces conference participants, and monitors and adjusts volume and quality of the telephone links. New digital telephone exchanges permit subscribers to link up or self-convene from two to six participants in a conference mode. Standard telephone bridges accommodate up to thirty conference connections, and in special cases thousands have been accommodated in one conference. Figure 7 illustrates two configurations for audio teleconferencing.

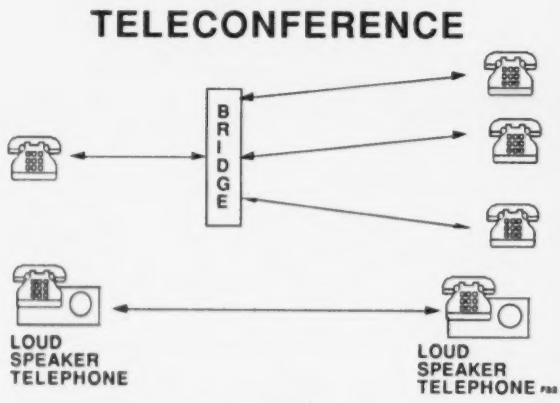

Figure 7
Audio teleconference is one of the earliest interactive modes of delivery of learning to the isolated or remote student.

Cable Television: Transmission of video is through coaxial cable or optical fiber directly from source to subscriber's television set. Several signals (channels) may be transmitted at the same time and selected by the tuner on the television receiver. It is possible to transmit signals in both directions to permit subscriber interaction. It requires very little power in comparison to off-air broadcast television and is cost-effective in densely populated areas. Most public cable operators are required by legislation to provide a dedicated education channel. Creation of programming is subject to the same cost/quality constraints as broadcast television. Channels available in VHF (2-13) and UHF (14-83) provide broad possibilities for scheduling, but cable operators tend to fill low channels with prime time revenue producing programming and relegate educational programming to unsocial times or to less accessible high UHF channels. In populated areas cable television has great potential for distance learning because it constitutes the Second Universal Network appearing in a large

percentage of the homes. Integrated with the telephone network for feedback and interaction further enhances cable as a mode to deliver effective distance learning programming to a broad spectrum of the population. See Figure 6.

Visual Electronic Remote Blackboard (VERB): This involves transmission of voice and textual material from instructor to student using regular telephone lines. The instructor's voice, as well as material created by the instructor with a stylus and drawing pad, is transmitted to the instruction site. Voice is reproduced at the distant site on a loudspeaker, and the textual material is reproduced by a stylus on the stage of an overhead projector. Second and third generation VERB systems capitalize on advanced technology to reproduce the image on white boards, computer screens, and in color modes. Hard copy of black or white board images is an option on newer systems. VERB has been superseded by audiographic conferencing which involves interface of voice and computer images over regular telephone lines.

Teletex: This is the generic name for a set of systems transmitting alphanumeric and simple graphic information via the extra line capacity in the vertical interval of the television picture. Broadcast and cable television systems transmit textual and graphic information during regular programming. Teletex information is decoded and displayed on a modified television receiver. At one time teletex held great potential for education, but technological advances in transfer of data curtailed much of the development work in this medium.

Telewriter: Microcomputers are linked through the telephone network to send and receive textual and graphic material. Data may be input from the keyboard of the microcomputer or by writing or drawing on a digitizing tablet. Information is viewed on all computer screens at the same time and may be converted to hard copy at any site. This mode is a synchronous mode of computer conferencing. Telewriter technology, as used to enhance audio teleconferencing, has developed into the mode known as audiographic teleconferencing.

Computer Assisted Instruction (CAI): Students interact directly with instructional material programmed into the computer system.
Computer Managed Instruction (CMI) The computer system is used to manage information on student performance, progress, and resources in order to prescribe, guide, and administer the instructional process to maximize learning efficiency. CAI and CMI may be carried out via telecommunication links by use of a modem on switched networks. CAI may function effectively by using the mail service to deliver discs to the learner. CAI emulates student/teacher interaction, provides immediate feedback, allows student to control pace and time of learning. CAI is an asynchronous mode of computer conferencing in which the student interacts with the host computer rather than with other computer users in the network. Instructor/student interaction on an asynchronous basis with the host computer establishes a feedback link and enhances the effectiveness of this form of instruction.

Audiographic Teleconferencing: Teachers and learners are connected via a combination of voice and computer, using narrow band telecommunications channels to transmit alpha numeric data, graphics, and freeze-frame video images. A telephone bridge connects students and teacher together in audio teleconference mode, and by using special software, students' computers are connected by modem to the teacher's computer. Information created on the teacher's computer, graphics tablet, frame store, or digitizer appears on each of the students' computer screens. The computer screen provides each participant the equivalent of an electronic blackboard. In older systems two telephone lines were required for carrying voice and computer data. In newer audiographic teleconference systems both voice and computer data can be transmitted on one line, resulting in much reduced carrier cost. See Figure 8.

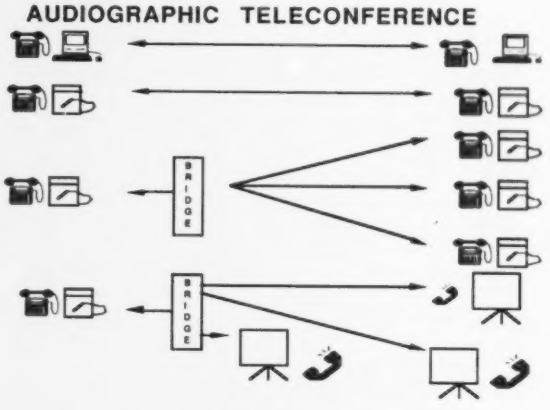

Figure 8
Audiographic teleconverencing adds the dimension of text, graphics and computer screens to standard audio teleconferencing.

Computer Conferencing: Two or more computers are connected using modems and narrow band telecommunication channels. Communication may be in synchronous mode to connect instructor and student in real time and emulate face-to face instruction, or it may be in asynchronous mode which uses a host computer

to store information for later access, such as electronic mail or bulletin board. When more than two computers are linked a data bridge is required. See Figure 9.

Satellite Delivery: A satellite located in geostationary orbit appears to earth stations as fixed in space and provides a broad "footprint"

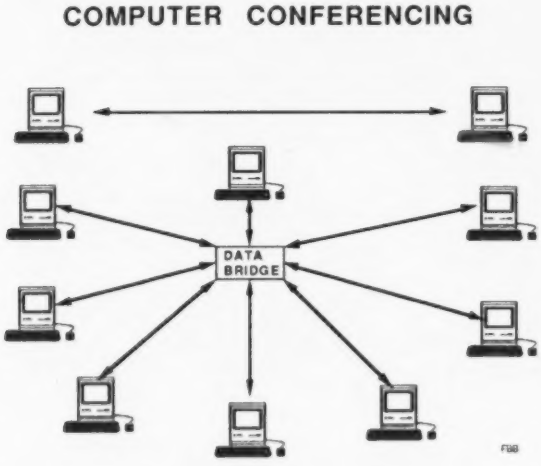

Figure 9
Computer conferencing enables the learner to interact with content and with the instructor in real time or at a convenient time.

from which it can receive transmissions from an "uplink" and re-transmit to any number of "downlinks" within the area of the footprint. This type of signal distribution is called point to multipoint. Each satellite has up to 40 receive/transmit transponders capable of distributing audio, video, and data signals. A number of satellites spaced in orbit can form a network capable of transmitting and receiving information to and from any point on earth. Satellite distribution can serve remote areas not linked by other telecommunication services. Satellites are most effective when used over a large geographic area with a large number of participants in local, national and international networks. Capable of bi-directional communication, satellite transmission of distance learning material is more often one-way with learner interaction provided by telephone link. Cost, programming constraints, terminal equipment, and lead time have restrained the small user. However, data compression, spectrum division, and advances in digital technology are reversing this trend to some extent. VSAT (very small aperture terminals) provide cost-effective bi-directional satellite delivery of narrow band programming of voice and data and are used extensively by corporations to link widespread offices. VSATs are an economical way to create a private network for business television (BTV). Educators make use of satellites operating at two different frequency allocations called C-band and Ku-band. C-band satellites were the first commercial carriers providing service to television and cable networks. They operate in the 6/4 KHz range and require relatively large receive dishes. The Ku-band satellites are more powerful, operate in the 14/12 KHz range, and, as they are more powerful, require smaller receiving dishes. See Figure 6.

Facsimile (FAX): This is a device and process consisting of a scanner to convert hard copy to an electronic signal which is then sent by modem on a standard telephone line to the receiving site where the signal is decoded, reassembled, and printed. Facsimile transmission has been possible since the 1920s. It was not until the mid 80s that the high-tech digital FAX made it possible to send facsimile images in seconds rather than minutes, and the cost of machine and carrier dropped to a point where FAX is now a universal component of every office. Although facsimile can been used as the sole mode for distance learning, it is most commonly used to provide hard copy interaction between learner and teacher as an enhancement to other distance learning modes. Developments in FAX transmission permit the FAX signal to be embedded in video for simultaneous delivery, during a videoconference, of hard copy such as evaluation and course materials.

Video Conferencing: Sites are linked by a video picture and voice using a telecommunications channel suited to the type of video required. Video conferencing can be carried out in three basic modes: freeze frame, compressed, and full-motion video, spanning bandwidths from narrow to wide. Point-to-point or multipoint conferences are possible and employ two-way video/two-way audio or one-way video/two-way audio interaction between sites. Any graphics or other material that can be picked up by a television camera can be displayed at all sites, and textual or graphic material may be annotated by presenters. Video conferencing emulates a face-to-face meeting and has the advantage of social presence which enhances the richness of information communicated. Digital technology using compressed or compensated video on the public switched telephone network (PSTN) has revolutionized the ease by which organizations can participate in cost-effective, fully interactive, real-time conferencing on a network basis. Business, industry, government, and education have adopted this format in a massive move to establish full-function, interactive communication for training and distance learning.

Compressed video teleconferencing has become very popular because of significant savings in

transmission costs and improved access, since the standard telephone network is used. Figure 10 shows the configuration for point-to-point and multipoint video conferencing using compressed video. Figure 11 illustrates the bandwidth choices available to conference users by comparing the number of standard lines equivalent to various compression rates.

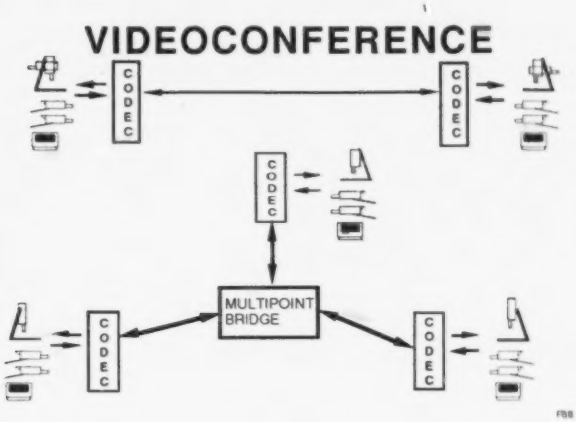

Figure 10

Video conferencing is the fastest growing form of corporate and educational communication providing full function interactivity between student and teacher.

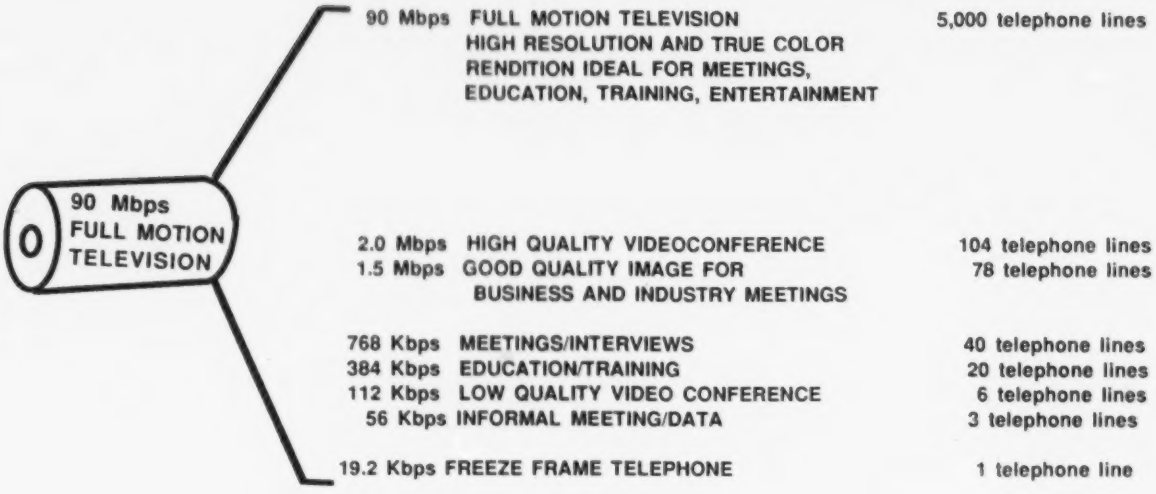
Videodisc: This is a plastic disc approximately 30 cm in size which is encoded by digital laser technology with up to 54,000 still images or 30 minutes of full motion video. Motion and still images may be combined on the same disc. Random access to images may be controlled by: instructions recorded on the disc itself, instructions programmed into the disc player, input to the player by bar code, or computer programs. Video disc is becoming one of the main sources of program material for multimedia applications. Coupled with a computer the video disc becomes a powerful learning device with good image handling, interactivity, image, and audio quality. The major drawback is the cost of original videodisc production and cost of interface equipment. Once produced, videodisc duplication cost is minimal and images are not degraded by use.

CD-ROM: (Compact disc read only memory): Plastic discs 12 cm in size are encoded by digital laser technology providing on-line computer access to a vast amount of audio and video information. A single CD-ROM disc can provide the learner with on-line access to huge data bases such as encyclopedia and research documents. This device is a key element in multimedia learning systems. It is cost effective for large stable data bases since this mass storage device is read only and requires complete re-manufacture to include new or updated information.

Business Television (BTV): This includes training, informational, and educational television production and programming to private or closed group audiences. In the past it was generally carried by satellite with telephone interaction. Recent developments in compressed or compensated video have opened up this mode of broadcast for BTV via digital lines on the public switched telephone network. BTV provides business and industry with a cost-effective way to disseminate information and training to multiple, distant sites without incurring high personnel, travel and time costs associated with on-site meetings. Major advantages are that live, interactive communication can be carried out, ensuring that all employees at all levels receive the same information at the same time. Business television users often establish their own network or participate in the increasing number of narrowcast networks established to provide service to a specific users with common goals, such as automotive dealers, financial consultants, or workers in penal institutions. These new networks tend to be industry-wide, cutting across corporate and product boundaries.

Compressed Video: The analog television signal as it is produced requires a tremendous amount of bandwidth to transmit (about 90 Mbps) when the waveform is combined with synchronization data and modulated unto a carrier signal for transmission. Digital technology permits encoding of the analog television signal in a much more efficient manner for transmission. Compressed digital video (CDV) reduces the amount of redundant information transmitted, and motion compensation results in only the changes between frames being transmitted. Compression rates can be as high as 6000 to 1 for freeze frame video at 19.2 Kbps to 60 to 1 for motion video at 1.5 Mbps. Compression is accomplished by a Codec (coder-decoder) which processes and encodes the analog audio and video television signal for transmission; once transmitted, a similar unit reverses the process by decoding the digital signal, returning it to analog which can be viewed on a standard receiver. See Figures 10 and 11.

Compressed video is expanding video teleconferencing in two major areas -- training and distance education. In satellite broadcasting, compression permits up to 20 channels to share one satellite transponder. Formerly one transponder was required to transmit wide band analog television signals. Compressed video reduces the bandwidth of television signals to the extent that terrestrial lines become practical. Digital transmission can be carried on standard public telephone



90 Mbps FULL MOTION TELEVISION
90 Mbps FULL MOTION TELEVISION HIGH RESOLUTION AND TRUE COLOR RENDITION IDEAL FOR MEETINGS, EDUCATION, TRAINING, ENTERTAINMENT

Figure 11
New digital technologies are providing access to more channels of communication by using bandwidth in a more efficient manner.

switched network lines on a bandwidth-on-demand basis using multi-band inverse multiplexers to provide the bandwidth needed for the quality of transmission required. The user pays only for the bandwidth selected and the time connected. See Figure 12.

Manufacturers are introducing new lines of videoconferencing equipment of multi-mode design which have ushered in a new era of "application-driven" video conferencing. New codecs, inverse multiplexers, and vision processors coupled with improved compression algorithms and digital dial-up data lines are changing the face of teleconferencing. The user can establish enormous cost savings by eliminating high-cost dedicated data lines of specific capacity for equipment that will access the required bandwidth on demand from the telephone switched network. Savings are further compounded when the user can select the bandwidth and compression for a specific application. In general the larger and more formal the group activity the greater the requirement for picture quality.

Videoconferencing has aspired to provide "in-the-same-room" quality of picture and interaction between remote sites. Full motion video, CD quality audio, and full two-way audio/video transmitted over fiber optic channels have indeed reached this plateau. Cost and installation lag prohibit wide-scale application of this vision for videoconferencing to all but selected geographic sectors. New compression technology and the effectiveness of compressed and compensated video for specific applications are helping to establish links with independent, geographically separated learners.

Multimedia: Each technology of communication as it has evolved and matured has exhibited unique qualities and capabilities useful in support of learning oriented opportunities.

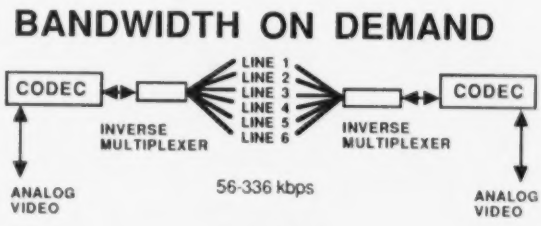

Figure 12
Digital video compression is making it possible to use the public telephone network to access the amount of bandwidth required while paying only for the time connected.

Multimedia is characterized by the convergence of these separate technologies into a whole that is far superior to the individual components. The cement of this union is the multimedia software which brings together computers, television, print, telecommunication, and mass information storage devices into a unified system. Multimedia systems not only exploit the beneficial qualities of each assimilated technology but provide a high degree of interactivity between the learner, developer, teacher, and learning materials. Multimedia will have tremendous impact on the way educators do business in the future. Educators and

learners will have a high degree of decision making in the design, development, and use of the learning experiences provided. One might say that both the instructor and the learner will be in the "digital driver's seat" in all aspects of the development of learning experiences and the later use of these experiences. Multimedia has been referred to as "digital fusion", representing the bringing together of digital technologies by the unifying power of the computer.

Multimedia is in its infancy; yet, as we approach the millennium, it is having significant impact on education and training. The operating paradigm today makes use of the "windowing" capability of computer software to inset and overlay information in any order and from a multiplicity of sources including computer disc, CD-ROM, video tape, audio tape, laser video disc. Multimedia software enables the instructor to organize information using the capability of the computer to program and manage information and provide a tailored learning experience for learners of all types, levels, and capacities. On the learner side multimedia enables the learner to plan, execute, and manage his or her learning experience at the rate, place, and time of the learner's choice. New digital storage, compression, and delivery technologies will, as they come on stream, provide ever increasing access to information bases and to live teacher/peer interaction. See Figure 13.

Conclusion:

Strategies for delivery of distance learning are in a state of flux and will remain so for most of the remaining years of this century. Educators cannot afford to wait for a stable platform from which to safely take the initiative to provide learning where it is needed. The best any of us can hope for is to make the necessary decisions from as solid a knowledge base as possible. This "primer" discussion has, on an introductory basis, placed past, present, and emerging technologies in perspective. The overview took a cursory glance at various technologies available to the user. Change is happening at a pace which finds new developments in use before periodical literature and even manufacturer's data sheets are updated. This pace is illustrated by the continuum of devices and processes arranged in approximately chronological order in Figure 1. It is of some comfort to note that most of the processes for delivering distance learning are still in viable use today. We must also consider how the space between innovations is closing up. Multimedia, which assimilates most former communications modes using the power of organization found in computer software, allows us to view the future with a great deal of optimism. Using this new learning system configuration is some guarantee that little of what we have done before will be a loss. Multimedia and new telecommunications technology ensure that today's distant students will have a place and a time to learn.

Figure 13
Multimedia is the converging of existing communication technologies by harnessing the power of the computer to access and manage information derived from almost any source..

THE GLOBAL CLASSROOM: A TELECOMMUNICATIONS EVENT FOR EDUCATORS

Noumea, New Caledonia

1. ABSTRACT

The paper focuses on an event that linked students and educators at multiple locations from Texas to New Caledonia. Technology at the various sites differed and the event showed how the existing technologies could be integrated to bring all parties together to learn about volcanoes, an issue of great importance to the Pacific area. This project is offered as a model for others to use in order to hold similar low-cost, cooperative, multimedia events for educational telecommunication purposes.

2. INTRODUCTION

Technological advances give today's educators new tools to explore exciting horizons and link people all around the globe. However, technologies often differ at various locations wishing to communicate making those links difficult. One may then abandon the planned link. On April 24, 1991, a group of educators overcame that barrier and linked multiple classrooms from Texas to New Caledonia using very different technologies at these multiple sites. The resulting event spanned seven time zones and crossed the international date line.

3. BACKGROUND

The historical climate for this event began in the fall of 1990 when a member of Hawaii Science Teacher's Association (HaSTA) asked to have a workshop on using Distance Learning--Technology resources. That idea was shared with leaders of the University of Hawaii Manoa's (UHM) MultiMedia Inquiry Group; and in less than a year, that request resulted in this innovative, international demonstration of multimedia technologies made possible by the involvement and cooperation of several groups. The event was sponsored by UHM MultiMedia Inquiry Group, HaSTA and the Department of Education Distance Learning Technology Program (DOE-DLT) in cooperation with PanPacific Education and Communication Experiments by Satellite (PEACESAT), and the University of Hawaii's (UH) Office of Information Technology with the Hawaii Interactive Television System (HITS). These groups enabled us to plan the global classroom event which originated in Hilo and was received by faculty and students in Honolulu, American Samoa, New Caledonia and two locations in Texas. Each of these locations used different combinations of technologies to access the program. This paper will highlight the technologies, organizational processes, and outcomes of the event which took place in April, 1991. It will include the perspective of the presentor in Hilo as well as the reactions of three groups--those at the various receive sites, those directly involved in the delivery systems and those responsible for the logistical support of the event. This project is offered as a model for others to use in order to hold similar

low-cost, cooperative, multimedia events for educational telecommunication purposes.

4. GLOBAL CLASSROOM FORMAT AND SCOPE

The format of the event involved Dr. Carl Johnson, University of Hawaii Hilo (UHH), Professor of Geology, teaching a short unit on Volcanoes from a studio in Hilo, Hawaii, which was transmitted to learners in Denton, Texas; Sanger, Texas; Honolulu, Hawaii; Noumea, New Caledonia; and Pago Pago, American Samoa. The range of technologies used included full-scale video, videophones, FAX, audio-only phones and satellite communications. Each site used different combinations of technologies to follow Dr. Johnson's presentation. The program could be seen on several public access channels across the state of Hawaii reaching many homes and schools. The volcanoes presentation was 20 minutes in length followed by a presentation on the various technologies being used and ended with a question and answer session which included a chance for all sites to comment on the strengths and weaknesses of the technology at their site. The moderator, located in Honolulu, orchestrated a roll call of participants with introductions and coordinated the question/answer/comment part of the hour.

4.1 PRESENTOR'S PERSPECTIVE - HILO SITE

(GMT April 25, 0100-0200 = April 24, 3:00-4:00 PM HST) (full-scale video, phone, videophone, videocamera input into videophone)

Although the experience described here emphasizes the technical aspects of distance learning, the choice of teaching material is itself critical. Many subjects of broad appeal are more effectively dealt with in a traditional venue such as the university classroom. Telecommunications becomes the method of choice when the target community is physically scattered and it is not practical to bring potential students together at a single learning center. This is most often the case with highly specialized material that is intensely interesting to a limited community.

The teaching unit chosen communicated information regarding a summer program of the UHH administered by the Center for the Study of Active Volcanoes. Each summer an intensive, experience-oriented, training program is offered to the staff of many of the world's volcanological observatories in monitoring and volcano hazard mitigation. The target community is thinly distributed worldwide at those places that have or anticipate having to deal with impending eruptive crises. In many cases, because of the exigencies of the hazard, personnel are not free to travel for periods long enough to acquire the necessary training skills. The teaching unit presented was a prototype of the introduction to this program, and the material was presented in a way that accommodated local access to technological resources. All of the remote centers were at least connected by audio communication links through PEACESAT via satellite and/or telephone. Many of the sites also possessed FAX and video telephone capabilities. Simultaneously material was being delivered within the state of Hawaii via HITS (Hawaii Interactive Television System). The nesting of these various technologies, concomitant with the interests each media served, caused us to consider our experiment to be something of a twentieth century allegory.

As the material was simultaneously addressed to diverse audiences, both educators as well as perspective students of volcano monitoring, numerous technical challenges were encountered during the actual presentation. It was necessary to respond at one level to inquiries coming in via interactive television while at the same time maintaining the content of material on volcano monitoring training over audio and videophones. During the presentation of the material in the teaching unit, the focus shifted from the television audience to the remote sites. One thing that became particularly clear during the telecommunications experience was the requirement for adequate support staffing at the point of origination. To be effective in delivering complex material of the sort for which remote learning is most appropriate, the teaching professional must be isolated as much as possible from the technical requirements needed to facilitate all of the communication links. This is something which will receive much more attention as we plan and carry out our next experiment in the delivery of technical material to remote audiences using rapidly evolving telecommnications technology.

4.2 AUDIENCE PERSPECTIVE - DENTON, TEXAS, SITE

(GMT April 25, 0100-0200 = April 24, 8:00-9:00 PM CDT) (phone, videophone, PEACESAT via ATS-3)

The day of the session had become night in Denton, Texas. It was the welcomed end of a 12-hour day for the Telecommunications and Informatics Laboratory at the Texas Center for Educational Technology. Goals for participation were simple: 1) provide technical support and backup communications (if needed) for the Sanger, Texas, site and its participants, and 2) demonstrate cost-effective telecommunications technologies to 6-8 University of North Texas College of Education graduate students who had expressed an interest in observing the session in order to augment their classroom experiences.

The Denton, Texas, site was a conference room with a videophone slow-scan television unit connected to the conferencing bridge at the University of Hawaii by way of a long distance telephone call. In an adjoining room, a PEACESAT ground station operator simultaneously monitored Dr. Johnson's presentation on the ATS-3 satellite and used a second phone line to maintain behind-the-scene voice contact with the Sanger site. A volunteer videotaped activities as observers occasionally circulated from the conference room into the adjoining control booth.

Observers were genuinely impressed with the performance of the combined technologies and the content of Dr. Johnson's talk. Even support staff became sufficiently interested to formulate questions for Dr. Johnson during the discussion portion. Observers were able to gain firsthand knowledge of how much is gained by adding slide-type illustrations, which were available through the videophone, to the voice-only mode delivered via ATS-3. Some also came to better understand concepts such as satellite turn-around delay, since the audio transmission from ATS-3 lagged behind the telephone connection by a few fractions of a second.

The exchange was judged by lab personnel as the best executed and most interesting of the approximately half dozen made available through the Telecommunications and Informatics Laboratory during the 1990-91 academic year. It is believed to have been the result of a clearly conceived purpose, carefully planned activities, and experienced support personnel at each site.

4.3 AUDIENCE PERSPECTIVE - SANGER, TEXAS, SITE
(GMT April 25, 0100-0200 = April 24, 8:00-9:00 PM CDT) (phone, videophone, PEACESAT via ATS-3)

Even though the session for Sanger, Texas, occured late at night, the teleconference was attended by a representative of the Department of Technology for the school district, the superintendent of schools, a computer literacy teacher, several students and two parents. The goals for the teleconference for Sanger might seem different from those of the University of North Texas and Hawaii, but in reality, they were simple: 1) demonstrate the accessibility of remote telecommunications for a small, rural, Texas school, 2) provide real-time, real-world, telecommunications activities for science teachers, computer teachers, students and 3) demonstrate to parents the value of telecommunications in the presentation of curriculum materials.

The Sanger site was much like that of the University of North Texas. A videophone was used for a direct land-line hookup; and, simultaneously, our PEACESAT ATS-3 ground station monitored Dr. Johnson's presentation. The session was taped for play back at a later time.

Members of the audience were impressed by the fact that Dr. Johnson's slides were sent via videophone for presentation to the Sanger site. Participants could see from the very beginning that science could be presented in a much more interesting format than that of just textbooks and filmstrips. Science became real and meaningful. Having an expert talking "real-time" to our students and participants was very impressive. The only drawback was that of time delay between the satellite and that of the videophone.

Even though Sanger has had other teleconferences, including some with people at the South Pole, this teleconference was extremely well received. It focused on the fact that "kids" learn by having hands-on, real-time activities. Having experts in their fields such as Dr. Johnson only added to the realization that students don't have to be passive listeners. They can now be active learners... knowledge users.

4.4 AUDIENCE PERSPECTIVE - NEW CALEDONIA SITE
(GMT April 25, 0100-0200 = April 25, 9:00-10:00 AM PST) (PEACESAT via GOES-3, PC, phone, FAX)

The PEACESAT communication system was recently installed in the South Pacific Commission (SPC) in Noumea, New Caledonia. As the system began to operate, it became an eye-opener to most of the members in this organization. The majority of the professionals in this program are used to other "normal" types of communication, such as telephone, FAX and electronic mail. The PEACESAT system offered something very special--it is very inexpensive to operate, provides facilities for telephone links, FAX coupling of computers to it and has the capability of use in conferences, meetings and for instructional purposes.

The presentation by Dr. Carl Johnson about the volcanoes emphasized the potential of this important tool/equipment for educational purposes for our 27 countries and territories of the South Pacific region. The pictures sent to other sites live via videophone were sent ahead by FAX to Noumea. Amongst the three people in the room (two educators and a scientist) the atmosphere was exciting and electrifying, that is to be able to participate in the discussions to learn more about the PEACESAT operation and its network around the Pacific rim. The quality of the reception in Noumea was excellent. For any regional dialogue or communications between all the SPC member countries, it will be excellent service to a lot of the tiny, remote atoll nations, where present communication is a big problem. If all the 27 island countries and territories were served with a PEACESAT station, education can reach children, the grassroots and others in these scattered and remote islands instantaneously.

The Noumea site did not have a TV monitor installed in order to see the other participants talking, however, this did not deter our enthusiasm in any way. As this new communication system was recently installed, it was an experience we will not forget. We look forward to learning more about this new technology and how it will assist the organizations and the Pacific Basin.

5. DISTANT EDUCATION DELIVERY SYSTEMS

5.1 OFFICE OF INFORMATION TECHNOLOGY - THE HITS PERSPECTIVE

While momentous in occasion, the Global Classroom demonstration was a coordinating challenge requiring extreme flexibility due to the geographic dispersion of the presenter and audience, the multiple telecommunication technologies, and the need for finding a time to practice with all. In retrospect, the critical component was the practice session, in conjunction with having identified program producer and content specialist.

A practice session is crucial for these types of programs due to the number of people, technologies and geographic distances covered. In this experience, there were many technical details that needed to be set up and tested--the Hawaii Interactive Television System (HITS), a two-way, video, interactive, television system connecting the Hawaiian islands; videophones; PEACESAT bridge; microphones for the speakers; and FAX machines. These sessions can help identify feedback problems, the flow of events, the setup of the room, placement of cameras and guest speakers and testing between two-way receive sites (UHH and UHM). In a dynamic experience such as this one, it was difficult to identify one program producer and one technical director since even until immediately prior to the program going on air, it continued to evolve; however, these roles should be clearly defined. Otherwise, the end result may appear fine but at a great toll to the support staff.

Since the practice session to test all these systems for the Global Classroom was not held, the support staff at UHH and UHM scrambled to accommodate the needs of the program. Many of the "bugs" had to be worked out while the program was in progress. The end result was a satisfactory program but proved the need for practice sessions which often get sacrificed because of heavy program scheduling. However, such time must not be neglected. This demonstration itself was very interesting and the process a challenging planning and coordination exercise. It was exciting to see multiple technologies being used to span the globe. It also taught us that planning, coordination, and practice are essential to a good program and even more so than in regular "in class" presentations.

5.2 THE PEACESAT PERSPECTIVE

For PEACESAT, 1991 represents a tremendous learning period for its distance education users throughout the Pacific; and the Global Classroom presentation experience was one more step in this learning process. Although PEACESAT has been actively contributing to the distance education experience in the Pacific for twenty years via ATS-1 and ATS-3, the recent reestablishment of a total Pacific footprint using GOES-3 with its advanced technological capability is allowing PEACESAT's educators to take great leaps in their technological mindset as to what can be done with telecommunication-assisted educational delivery. The combination of HITS, PEACESAT/GOES-3/ATS-3 and bridged telephone connections delivering education via interactive full-motion and freeze-frame video, facsimile, voice, and data was a mind-boggling reality to all PEACESAT participants of what the future may hold for distance education.

Two immediate and specific insights brought about by this telecommunication experiment for PEACESAT were: 1) the necessity of consistent use of multi-application distance education practices and, 2) the need for standardization of PEACESAT ground station sites in the technology that is currently possible. "Practice," as termed elsewhere in this paper, means something different to the PEACESAT users. Practice must involve real content or else the practice does not translate to users. It was also made very clear to PEACESAT Headquarters that all sites need videophone capability now that the GOES-3 technology supports its application, and this Global Classroom presentation provided the impetus for an across-the-board grant application for this technology.

Innovators in distance education delivery need to be encouraged to go beyond one-time events to regularly scheduled sessions, so that, by their example, others on the edge of the technology will be tempted into the realm of 21st century educational delivery systems.

6. LOGISTICAL/SUPPORT SYSTEMS

6.1 CENTER FOR TEACHING EXCELLENCE - CTE PERSPECTIVE

The Inquiry Group coordinator at the Center for Teaching Excellence (CTE) at UHM provides logistical support to events sponsored by the MultiMedia Inquiry Group and other faculty-led Inquiry Groups associated with CTE. The responsibilities were primarily to facilitate communication between the core group of event sponsors and to create promotional materials to be used in Hawaii. This involved coordinating the initial planning meetings and also setting up an e-mail "loop" among most of the core group. A flier was drafted publicizing the event and distributed to core group members for their comments. A camera-ready flier was then created and used to publicize the Global Classroom to educators in Hawaii. A one-page resource sheet listing distance-learning contact persons in Hawaii was developed and was available to Global Classroom participants on the day of the event. CTE distributed materials to the UHM community while the DOE-DLT program distributed the flier to teachers in the public school system in Hawaii.

Expenses incurred in publicizing the event consisted of about one day of staff time necessary to create the flier and resource sheet, duplication and mailing of about 200 fliers

to UHM faculty (open market cost about 35 cents per sheet) and the cost of locally FAXing about six pages of information to the core group during the creation of the promotional flier. These expenses were absorbed by CTE in support of the MultiMedia Inquiry Group.

6.2 THE DEPARTMENT OF EDUCATION - DISTANCE LEARNING TECHNOLOGY PERSPECTIVE

The Global Classroom teleconference demonstrated how the myriad pieces of technology fit together. Dr. Johnson had previously been a guest speaker for some of our Hawaii schools, via the still-frame videophone. Students from several different schools had conducted audio conferences over the PEACESAT telephone bridge. Other students had visited PEACESAT and were able to talk with people in the South Pacific via radio transmission. Department of Education staff had used HITS to conduct two-way interactive conferences on various topics throughout the year. Students on five different islands had received one-way video and two-way audio during an Advanced Placement Calculus class over HITS between the islands and through the public access channels of several different cablevision companies across the state. The April, 1991, teleconference was the first time we were able to simultaneously utilize all of these methods of communication, plus a few others, such as voice over satellite. Although all schools didn't actually participate, the teleconference potentially could have been viewed within the state of Hawaii by over 90% of our schools and 75% of the homes.

We have learned from the teleconference that mixing of technologies can work, and it vastly expands the areas in the world that can take part in such a conference. In education, we must provide teleconferences that can be shared nearly everywhere regardless of the sophistication of the technology in that location. This teleconference did just that.

The one area observed in this and in other teleconferences that may improve future teleconferences would be to break the lecture paradigm. As an example, it may have been more meaningful if Dr. Johnson's lecture (which was excellent) had been on a videotape and distributed to all sites for viewing prior to the actual teleconference. Then the interactive part of the teleconference could be done as we did it during the Global Classroom event.

6.3 HaSTA'S TELECOMMUNICATIONS EXPERIENCES

The Global classroom event materialized from an initial request made by a HaSTA member for a workshop on using Distance Learning--Technology resources. It was appropriate that it be broadcast across the state of Hawaii so that HaST members could view the event. It is not surprising that such a request came from this group since HaSTA has over a decade of experience using various forms of telecommunications technology. In the early 1980's a newly-elected president of HaSTA suddenly had to move to the island of Hawaii. Typically, the HaSTA officers were from the island of Oahu. Instead of electing a new president, HaSTA board meetings were run by its president via audio speakerphone from Hilo. The meetings were even more effective and efficiently run than the all face-to-face meetings on Oahu. Ten years later HaSTA has again begun using telecommunications for its monthly board meetings. Now HaSTA neighbor island representatives are able not only to hear each other but also to exchange still, black and white images with the other HaSTA board members meeting on Oahu. The Hawaii DOE has established audio/videophones in all public schools in Hawaii. These have been made available for these and other meetings of professional groups to permit teachers and students statewide to actively participate in their organizations.

Another aspect of telecommunications formerly used by HaSTA involved electronic mail on a University of Hawaii computer to submit articles for the periodic newsletter. Members having news for the editor can easily send it by computer mail thus saving the editor from having to retype the news items. With electronic mail systems now sponsored by the DOE, this technique is expected to resume once again.

In 1989, the HaSTA Chemistry Section created an electronic bulletin board on another UH computer for use by any of its members needing or having information regarding chemistry education. This has been used to allow some of the individual members to organize "electronic field trips" using techniques via computer, audio and videophone to provide classes information about careers, scientific research, and environmental issues.

7. POST-EVENT OUTCOMES AND FUTURE DIRECTIONS

In addition to the grant application that was discussed in the PEACESAT PERSPECTIVE section, there have been other outcomes. The success of this inaugural cooperative effort has led to the establishment of an informal association of the cosponsoring groups called the International Telecom 21 Project Advisory Council. Through periodic electronic mail exchanges, the group has maintained contact in expectation of sponsoring similar projects using interfaced multimedia telecommunications technologies. In the fall of 1991, HaSTA, in cooperation with the Hawaii DOE and Hawaii FYI computer network, set up a statewide bulletin board called Science-Technology-Society (STSBB). Anyone with a computer and modem can (1) establish a free account on Hawaii FYI and (2) use STSBB to read or write messages via a free statewide phone network. Ironically, though designed mainly for Hawaii residents, the first item entered on STSBB came from Sanger, Texas!

From the Global Classroom event, we have discovered an exciting way to work together

in developing innovative means of information exchange on a local, regional, national and international basis. Different perspectives from those involved, when shared cooperatively, will indeed expand horizons for linking people around the globe.

Special thanks to Joy Shirokane, Lisa Poulos, and Susan Pang for their technical knowledge and skill. Special thanks to Joyce Ogawa for her help in preparation of the manuscript.

Evolving Educational Environments: A Projected Impact of the Recent Digital Revolution

1. ABSTRACT

Digital Revolution has influenced most aspects of our lives. The computational opportunities abound. The communications facilities have networked most computers. Personal computing has reconstituted our rationality. Numbers have become a language of their own and so on. The general impact of such an explosive change depends upon the structure of the culture absorbing the effects. However, the educational environments are particularly important since education and reason have been intertwined to discard bias and ignorance. In this paper we examine the dynamics of the profound technological change within the context of educational systems ranging from the kindergarten to the doctoral research centers.

2. INTRODUCTION

Traditionally, educational environments have been confined to schools, colleges and universities for instructing students. Modern communication systems have a special role in the society since dialogue (an interactive process) is gradually replacing learning by osmosis (a more subdued and passive process). We integrate these incipient effects that the computer and communication systems are bringing into the educational environments and present the emerging changes. The influencing factors ranging from stand alone micros to classic networks are matrixed onto the educational institutions ranging from grade schools to graduate centers. The impact of recent significant innovations such as ROM disc and modern AI languages will also be presented in the main body of the paper.

Some products and technologies will be more significant than others in different sectors of the educational environment. In this paper, we will isolate the nature of impact of network technology upon collective group research and contrast it with the nature of the impact of passive information retrieval environments such as grade schools.

3. SUMMARY OF MAJOR SOCIO-ECONOMIC INTERACTIONS

When two major and influential components negotiate an interactive process, four distinct stages of interaction are generally identified. First, when the interaction starts to emerge, there is a phase of superficial enthusiasm in which rather uninformed parties play up the major benefits that can be derived by the interaction. At the stage, since the process of interaction is not visualized in any detail, the process is seen as being one-sided, and the emphasis is focused upon what the impactor is going to do to the impacted. These benefits are exaggerated to convince powerful socio-economic groups. A certain amount of financial and power-base is built to manage the infancy of the interaction process.

Second, when a substantial amount of resources have been expended in building a pioneer system (which essentially is a forced fit of the impactor upon the impacted) to realize some of the benefits of the first stage of the interaction, many well informed experts scrutinize the entire process from both (the impactor and the impacted) points of view. At this second stage, the process is stream-lined and the experts attempt (to some extent) to make the next system graceful, integrated, efficient and optimal. Redundancy, waste, and sub-optimal design of sub- systems are generally eliminated.

Third, when the system is functional yielding marginal results, the age old rules of micro-economics are applied to the composite impactor-impacted system. The benefit-to-cost ratio of the system (as it exists at this second stage) of its evolution are scrutinized by accountants and managers. Now the experts already on board in the second stage propose a more cost effective integrated system which is designed from its very conception and from both points of view to satisfy the needs of the impacted and the technological limitations of the impactor. Since the recipient and the beneficiary of the system is likely to pay the price of the system, considerable managerial authority is exercised in having an acceptable, optimal and profit making system.

Finally, when the new system is designed and constructed, experts from both disciplines would have fused their resources, goals and expertise to offer an new environment which becomes well integrated and well founded. This system now becomes a platform for other incremental changes that technology may bring to a mature and established technology in its own right. We foresee that the new educational environments of the future can be only be evolutionary (like our communication systems) and are likely to exhibit these stages of evolution. It is our hope that the path towards the new educational environments of the twenty first century can be shortened and streamlined by early cooperation between experts from the digital industry now in an explosive phase of expansion and the gurus of educational systems who are willing to accept ideas but reluctant to implement the change.

These four stages of evolution have occurred in many areas where the impactor can substantially modify the impacted. Typically in the evolution of the automobile industry, the four stages can be identified as (a) realization of the internal combustion engine to provide the motive power, (b) the motorized horse-carriage, (c) the redesign of the internal combustion engine for automobiles and (d) the stream lined auto. Aircraft industry, farming industry, war and defense industries all exhibit such stages before maturity is reached. In other cases where these four stages are discernible are the credit card, microcomputer, and communication (all aspects from signalling, switching, transmission, to optical systems) industries.

These stages occur only if the two interacting components are significant, balanced and have the potential to modify each other. When one is insignificant compared to the other the process becomes absorption and the consequences are not worth the study. When the power balance is biased, the the duality of the modification process leading to greatly rewarding mutual benefit is stifled. The four stages of modification are more likely to be present in democratic and open societies leading to an accelerated progress towards optimal system.

All these four phases of the interaction process may not be discernible in every situation. In some cases (e.g., robotic technology in Japan), a quantum jump from the first stage to the fourth stage in one rapid leap may be evident. The impactor and the impacted have distinct technological, economic, social, and cultural bounds which influence the intensity and the duration of these aforementioned stages. In some cases, (computers in medicine) multiple ripples can also be identified. Where the interaction between the impactor and impacted (e.g., fiberonics and communications, optical processing and computing, etc.) are based upon the solution of crucial technological breakthroughs, each partial solution causes a ripple of its own. These stages of oscillatory convergence to an optimal state (if there is one) are simply a manifestation of the migration of one stable operating condition to another due to a profound change in the environment.

4. DIGITAL REVOLUTION AND EDUCATIONAL ENVIRONMENTS

Here the impactor and the impacted both have enormous inertia and can dramatically influence each other. If the interaction is only circumstantial, then the path of progress is likely to littered with exploiters, whose objective is to secure a financial gain while the encroachment of digital revolution upon the educational environments occurs undaunted. On the other hand, if the optimal modus operandi in envisioned, then the path of progress can be demarcated by clear cut milestones and the transition can indeed be smooth. One example where the global communication industry has established such well accepted milestones (the common protocol, the signalling network, the stored program controller to monitor the switching functions, etc.) is the phased introduction of Integrated Services Digital Network (ISDN). The second, perhaps the more profound example in the establishment of the Open System Interconnect (OSI) model for communication.

4.1 Discussion of the Educational Environments

There are three major factors shaping the nature of the impact of the digital revolution upon the educational environments. First, consider the digital revolution as it has influenced the computer and communication field. In context to the educational systems, the three major consequences of the digital revolution are (a) modern computing systems, (b) modern communication networks, and (c) modern mass media systems.

Second, consider the educational environments that become the recipients of the impact. The effect can vary significantly in three basic aspects of educational systems; (a) nature of the education provided and the educational facilities (kindergarten to doctoral centers), (b) the spectrum of disciplines taught (fine-arts to abstract/mathematical sciences), (c) and the extent of emotional support required to teach (occasional touch-contact to purely factual communications). Fortunately, to a certain extent natural grouping exists, i.e., in the kindergarten, a low level of all disciplines is taught with a high extent of emotional contact or conversely, a highly selective discipline is communicated (or discussed) with no emotional content in doctoral centers.

Third, consider the integrated effects of the impact per se. Here again, it can be visualized that considerable simplicity can be attained by limiting the areas of study to include only highest impact. For instance, the ROM disc technology is likely to impact the lower end of the educational spectrum since the communication is not likely to be oriented towards interactive global database

search thus curtailing the impact of communication networks on kindergartens, and highly emotionally supported environments are not likely to be globally networked. Conversely, in highly directed research center where factual information is exchanged there is little or no emotional counseling. Where the discipline taught needs high reason and logic, the need for fourth generation languages and their compilers may be identified.

However, in a general sense, every technological aspects will each interact every educational environments thus splintering the systematic appraisal into too many different areas of study. If a certain attribute of the educational environment is likely to be strongly influenced by the technological revolution, then the effect of the impactor has to be interwoven with other (similar) effects of impactor-impacted interaction. The four stages of the evolutionary process thus gets modified by the ripple effect of similar stages of other interactive processes.

5. BASIC SYSTEM MODEL

For the basic model in this study, we have borrowed the concept from decision support systems. In this version, the model (Fig. 1) consists of three major components: (i) a front-end processor to deal with the dialogue between the user of the system (student in this case) and the system (machine based educational systems (MBES) whose attributes will be developed), (ii) a knowledge-base manager with an internal knowledge base and an external knowledge base, and (iii) a model manager that fits the query of the user in a mathematical context to query the knowledge bases and provide a piece of information back to the dialogue manager. The process may cover numerous transactions involving the participation of the three major components. The student learns to ask the right question to the dialogue manager over a period of time. This process of learning the communication skills occurs elsewhere in society. The system handles complete queries the first time, but interacts with the student till the query is complete in the interaction mode. In the forward communication mode, pertinent information for the "course" that is being taught will be presented as a "teacher" would present it to the class.

This model lacks the ability to provide human-emotional component of the kindergarten environment. For this reason, we have modified the model (Fig. 2) to include a configuration that includes teaching (or even nursing) staff that can provide dialogue, model and knowledge base capabilities at a human level. When the query is rudimentary the human systems with the same three functions will suffices. When artificial intelligence is invoked by higher level students in the query process, the system will suffice. In the real world, it is to be appreciated that a blend of the two will be necessary to handle the overall educational spectrum. This brings us to the first model of an instructor assisted MBES which is much like a classroom full of networked computer workstation with one or more instructors to complete the needs of students that need a "teacher".

5.1 Role of the Communication Networks

The modified model shown in Fig. 2 or its derivate has all the attributes for the educational systems. The network aspect has numerous impacts. The knowledge bases can be widely distributed and accessed via a LAN, MAN, or a WAN. Likewise, the query points can also be widely dispersed and may access the "classroom" via a network, and the model matching can be done at any location. The class thus becomes a collection of access points and the MBES becomes a logical network which will invoke "teacher" assistance if there is need for a real human tutor or a video portrayal of the "long-distance-professor".

5.2 Role of Microprocessor Industry

Microprocessors for the implementation of basic function in all the basic components (networks, intelligent terminals, local and remote data base managers, etc.) of the model in Fig. 2 are essential. The function and feasibility are not the issue, but instead the cost and real-time response time that make the hardware adept for the MBES. Microprocessors and customized chips will appear for MBES over a period of time and will facilitate the smooth "class-room" functions over the logical network that could function much like any other data communication facility.

5.3 Role of CD ROM Disc Technology

This recent technology makes the concept of MBES a step closer to reality by reducing the access time and network costs for a large fraction of "classes" for the lower end of the educational environments. Any documented and published information becomes immediately available the "class". The plummeting cost of encoded CD's and the low cost of access to a centralized mass storage system makes massive amount of information available to every class.

5.4 Graphic Interfaces and Video Compression

Both have a significant impact on display and access costs. Video compression and the subsequent access of paintings and major performances opens new doors to the study of fine arts. Such facilities are now feasible in classrooms and in real-time. Access by individual students to scrutinize major plays and performances can be provided via MBES to any high speed display device. The emerging high definition TV (HDTV) standards can only enhance the use of graphics to provide a visual mode of communication to the students in all stages. The learning process is thus accentuated by a perceptual reinforcement and video sequencing. The MBES is capable of providing this mode of learning to students with various learning abilities.

6. EXISTING PLATFORM FOR MBES

It is easy to see that there is no real obstacle to building a local MBES for a campus based university or for that matter an urban university such as the City University of New York with numerous colleges. However, when the geographic areas are vast and information is widely dispersed, network architecture and control can pose an implementational problem. For this reason, we have investigated the architecture, control and implementation of Bellcore's IN/2 (Intelligent Network II, Fig. 3). We see that all the functional requirements of MBES can be handled by this architecture. The architectures of Bellcore's IN/1 and IN/1 + are nor considered since the concept of "service programmability" is absent. It is our belief that having this flexibility via the service logic interpreter (SLI) permits the development of new courses and individualized teaching styles of different faculty members.

The functionality of the STP/2 also need some modification. The reason is that the database for signal transfer point has to be subject/concept-driven and not address-driven like in the conventional IN/2. We do not see this as a major concern because the disciplines have been already grouped hierarchically. Such hierarchies (such as the Dewey decimal scheme) are used by most libraries. To take advantage of the design and feasibility studies by numerous operating companies and Bellcore, it is proposed that any questions from the "class" be identified by the subject/concept content. When the root of the query is identified, then the location of the database or the "expert" be then obtained from the service control point (SCP). The access is then complete via the routing information thus secured over the signalling network. This part of the educational network will be the same as any other intelligent network.

At the implementational stage we do see two problems of an ill-defined MBES. First, the identification of the root can be misdirected by the lack of complete information about the question from the "class". Second, far too many databases and "experts" may be identified. Both these problems are not surmountable if the search procedure is delayed till the "student" is queried enough by the dialogue interface to properly the nature and the subject content of the question. The teachers in conventional classrooms use this procedure, when the student asks a question that is incomplete or irrelevant to the topic under discussion.

If a universal educational environment should be able to handle all "classes" ranging from kindergarten to graduate centers in all the subjects with open student enrollment, then it appears that new constraints are necessary. New standards, protocols, and functional layers for the MBES environment will be essential.

6.1 A New Open System Educational Interconnect (OSEI)

If a new OSI environment for the MBES "class" is necessary, then protocols for MBES functions have to be developed. One of the initial steps would be to define the architecture of the MBES. In Fig. 4 we propose a single knowledge base global MBES. Miniaturized versions of this will serve a campus. Versions of these separated by subject matter can be shared by many universities. Individualized versions of these can be built by each faculty members to be responsive to department needs for registration, advising, and administrative tasks. Modifications to these knowledge bases is effected on an incremental basis by the "expert" faculty committee. It seems that a whole new creed of knowledge worker may be initiated at both the faculty and the student levels.

In the conventional OSI model, the application address is provided by the user. In the OSEI, the dialogue manager (local or networked that monitors the student interaction via his intelligent terminal) provides the address of the database or the "expert". Hence we see that the communication in the OSEI is a two step procedure. First, an AI based network interface acts as a buffer between the knowledge bases and the "students". Second, the information to identify the right knowledge source is interpreted from the query and it is at this stage that the address translation takes place (via the STP and SCP of IN/2 architecture) and the physical address of the source is used to secure the information sought. This information is then extracted and communicated to the student till the all phases of interaction (spanning numerous transactions) between the student and the MBES is complete.

For privately owned MBES's the protocol and the knowledge base search need not be optimal, even though standard interfaces and dialogue handlers will will permit quicker expansion and integration of many MBES's. However, "classes" operating under standardized education platform will permit globally dispersed students to be educated by globally dispersed knowledge bases, faculty or "experts". The deployment of MBES's is likely to follow the evolutionary pattern of any other communication network starting locally and growing steadily. It is also likely to make the students think coherently, logically and precisely to interact with the MBES (which is itself a coherent, logical, and a precise system). This aspect of student learning is similar to that of the students learning to program in a new computer language or children learning to interact with their "teachers". However imprecise the query patterns may be during the initial learning phase, they are going to become precise and optimal over a period of time. We do not see this as a problem since all early man-machine interactions are far from optimal. Learning the precise MBES dialogue is a step towards achieving proficiency in the students knowing what is it that they want to know.

For low level educational environment (such as grade

schools), the MBES needs considerable human component at the dialogue interface level and the requirement can be easily built in the physical class rooms with a blend of real teachers and intelligent terminals. Individual attention and emotional care for students is necessary. It is our hope that the actual communication of factual information to these young students (by the real teacher) will be reduced considerably and these teachers will be there to provide the human aspect of the learning environment (typically, motivation and care) to the students. Facts, documented information, video pictures and other nonemotional education will by communicated by MBES.

6.2 Implementation of the MBES

The introduction of the MBES will not be smooth process in the unionized school systems and the problems in these schools will be similar to those encountered by automobile manufactures approaching a automated, streamlined and robotic facilities. Such transitions have occurred in coal mining and steel industry, are occurring in auto industry, and have already occurred in computer industry in the US. Resistance and fear from those unwilling to undergo the change and retain the status quo is documented in all aspects of socio-economic interrelations between the participants.

6.3 Proposed Partial Implementation

The standards are absolutely essential to build and integrate a universal MBES. However, small campus wide MBES's can be built to evaluate the feasibility and the student response to the system. This phase of the introduction will facilitate the design and development of the "dialogue processor" to interface the students and the system. The range of variation of this dialogue processor can vary significantly from subject to subject, from class to class, and from culture to culture. Hence any design experience in building this dialogue processor can only benefit the effective usage of the overall system.

7. CONCLUDING REMARKS

We have presented an approach to computerization and networking of the educational environments. The role human emotion in teaching and learning is not undermined; instead the role has been identified and given back to human beings. Mechanized systems are limited to the delivery of knowledge in a methodic and systematized way while "teaching" and to the practice of artificial intelligence, information retrieval, and providing the information to the "classroom" or to the individual student in a rational, logical and coherent fashion instantly and inexpensively. These systems relieve the human teachers of being emotional and rational at the same time. The technology to take this bold step forward appears is here; the question yet unclear is whether the society can accept new ways to teach and learn effectively.

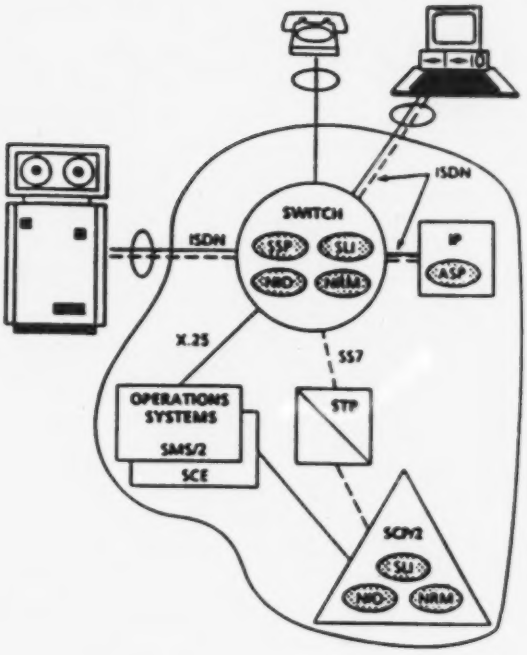

Fig. 3. Typical Architecture of Intelligent Network (IN/2) SLI Service Logic Interpreter; SCP Service Control Point; STP Service Transfer Point; NRM Network Resource Manager; NID Network Information Database; SSP Service Switching Point; SMS Service Management System; SS7 Signalling System 7; SCE Service Creation Environment; X.25 protocol for signalling and control of network. ISDN integrated service digital network lines. ___ Transmission Path; ---- Signalling Path.

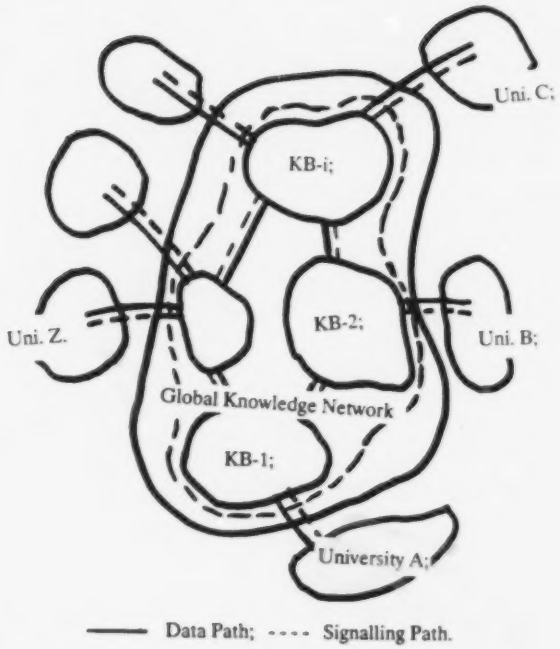

Fig. 4. A Proposed Architecture for MBES with Open System Educational Interconnect. Here the various universities have access to networked massive knowledge base. The front end processors at the universities have the "dialogue processors" and pass only pertinent queries to the knowledge base network. The "model matching" (depending upon the subject matter of the query) may be handled in the knowledge network or at the local universities. The authorization code supplied to the univerisities will permit or deny access to the users.

THE ROLE OF KNOWLEDGE TRANSLATORS IN TELECOURSES: A CASE STUDY

Angelina T. Wong
Extension Division
The University of Saskatchewan
Saskatoon, Canada

ABSTRACT

The University of Saskatchewan telecourse model attempts to create a positive teaching/learning environment that utilizes a team of knowledgeable and caring "knowledge translators." Television instructors, assisted by a team of local facilitators, help groups of widely dispersed students learn the skills required to translate new information and ideas to contexts that are personally meaningful. The rationale behind this distance education model and the experiences resulting from the delivery of telecourses in English, History, Psychology, Mathematics and Native Studies are discussed.

Teaching and Learning at a Distance:

Distance education has emerged in the last 20 years as one of the fastest growing areas of post-secondary education in both advanced industrial and developing countries. The primary attraction of this form of education is on its potential to improve equality of education opportunity through increasing access to large numbers of people and to various disadvantaged groups. The nature and structure of distance education varies between and within countries, but the processes and techniques adopted all aim to free learners and educators from the temporal and spatial constraints of traditional education.

While distance educators have tended to appeal for government funding and support by focusing on the the potential ability of distance education to provide cost-effective education and training for large numbers of people without massive geographic and social dislocation, the efforts of many distance educators have been concerned with the individual learner. The distance education literature is filled with accounts of the struggle to personalize the teaching/learning materials and the relationship between spatially separated teachers and learners.

Providing education to students learning at a distance involves a variety of activities which can be categorized into two phases: (1) the design, development, physical production and storage of instructional materials; and (2) the bringing of learners into contact with the materials and resources relevant to their learning. (Pratt, 1987). Although the rapid growth of instructional technology has provided educators with a wide range of media to achieve the these tasks, one teaching function poses a special challenge--- that of stimulating student interaction at a distance. Within university distance education, various institutions have developed courses using different combinations of print, audiotapes, videotapes, satellite and cable television, radio, microcomputers and the telephone.

A review of the research literature reveals that most teaching functions can be performed using most any one of the above media. When one medium is compared to another for effectiveness of instruction in any given subject matter, significant differences are seldom found. When it comes to learning, however, there is commonly more variance reported within than between media, leading to the conclusion that how a medium is used in the learning process may be more important than what medium is used. Factors that influence quality of learning in face-to-face settings also influence the quality of learning where educational media are employed (Clark, 1983).

Telecourses in Distance Education:

Since the establishment and public success of the British Open University, post-secondary institutions around the world have emulated their practice of preparing courses for students living at a distance from the main campus. While television broadcasts played a prominent role in providing a "window on the world" for the Open University students, the high cost of television production has prohibited many institutions from using the medium extensively as part of a multi-media teaching package. Television, as a technology, has evolved into many forms. In addition to microwave or cable, it is now possible to distribute the signal via satellite or fibre optics. Videocassettes, video discs, and microcomputer-based systems all enhance control and flexibility for the learners.

From the institutional perspective, the presentational strengths of television is often less important than its distribution potential. In an era of concomitant budget constraint and community demand for access to higher education, the use of low-cost television to reach students located at a distance is an attractive alternative for educational planners. In the 1970s, Stanford University in California pioneered the relay of classroom lectures to a range of different sites where local face-to-face tutors handled questions following the viewing of a lecture. This method is called Tutored Video Instruction (TVI) in Britain and has been used extensively for the continuing education of various professional groups.

In Canada, our Maritime universities, via the DUET system (Distance University Education via Television), successfully

used one-way videoconferences to deliver courses to distant students in the early 1980s. A television signal was sent by cable to designated locations with a return telephone link to the studio classroom. Telecourses in the mid 1980s (e.g. courses produced by the Knowledge Network of British Columbia and TV Ontario) incorporated live-interactive television with other learning materials such as student study guides. Live, interactive television has been defined as "that which is offered via satellite or microwave delivery systems in real time to students, with immediate talk-back capability with the instructor" (Whittington, p. 47)

The University of Saskatchewan Telecourses:

The model developed by the University of Saskatchewan draws on the experience of other institutions but has incorporated certain unique features. Like some other institutions, we provide the students with an opportunity for live interaction with the television instructor as well as access to student support services such as telephone counselling and on-site tutors. Unlike many other institutions, our television signal is "narrowcast" to designated sites such that the programs are not available to the general public. The insistence on a learning group based at specific locations reflects our believe that learning in higher education is facilitated by an opportunity to develop skills of analysis, interpretation and application in the company of learning peers. We fully realize that this is done at the expense of student control over time and pace of study. However, evaluations conducted over three years (Wong, 1988; 1989; 1990) have shown us that the majority of our students feel positive about this approach. They appreciate having access to some of the best lecturers on campus, and many feel they have developed a greater sense of affiliation with the university.

Like some other universities, our choice of television as a medium of instruction has been based on a number of economic and political factors in addition to pedagogy. The small and widely dispersed population of Saskatchewan (about one million people in a province three times the size of the United Kingdom) makes it financially unfeasible for the university to offer face-to-face courses in many small rural communities. In 1987, after several years of increasing enrollment with no corresponding increase to the university program budget, our College of Arts and Science imposed a quota which resulted in hundreds of qualified students being turned away. When a "seat sale" on the satellite Anik C was offered by Telesat Canada, our administrators decided to invest in the development and delivery of introductory English and History courses to 13 rural communities. The success of the pilot program resulted in the addition of courses in Psychology, Mathematics and Native Studies over the next three years. All of the television instructors had reputations of being excellent teachers as well as scholars in their disciplines. The recent establishment of the Saskatchewan Communications Network (SCN) has provided further government funding and a mechanism for province-wide delivery of our credit telecourses to over 50 learning sites.

The basic format of the weekly telecourses consists of a 10-minute orientation and review at each local learning site, a 60 to 90-minute live television presentation, a 30-minute off-air discussion led by a local facilitator, a 30-minute on-air discussion with the instructor, and a 10-minute wrap-up at each local learning site. The orientation and wrap-up are conducted by facilitators recruited from the local community. Dramatic vignettes, slide shows, video clips and interviews are pre-produced and incorporated into the live television presentations. The students could also consult the instructors individually via toll-free telephone lines at other designated times of the week. Each telecourse is complemented by a course guide, a package of readings, and a variety of textbooks.

The Role of Knowledge Translators:

The emphasis placed on the cost efficiencies and universal access which distance education methods and technologies can achieve often detracts attention from the need of individual learners to gain control over their lives and environment. Designers of telecourses often attempt to meet the needs of individual learners by selecting teaching/learning strategies that promote dialogue between the teacher and the learners as well as among learners. The recruitment of local facilitators for the University of Saskatchewan telecourses reflects the designers' concern with providing learners with assistance to relate and apply new knowledge and skills to relevant contexts, for example, "How do 19th century Victorian love poems relate to life in rural Saskatchewan?" and "How can the concept of differentials be used to estimate how much ice has collected on my grain silo?" The television instructor, as the subject matter expert, is the chief "vehicle" for helping the students bridge this gap. Given the spatial separation of the instructor and the widely dispersed learners, other facilitators can be recruited to guide this quest for personal relevance.

There are a number of models which are useful for identifying the instructional elements which contribute to this teaching/learning process. Pask (1976) formulated a "conversational theory" that states that learning occurs during "conversation", or interactive dialogue among participants in the learning process. Holmberg (1983) contended that distance education should have the spirit and atmosphere of a conversation between the students and the supporting organization. Students can have "real" interaction with instructors, tutors and counsellors via written and/or telephone exchanges as well as simulated interactions via pre-produced course materials. Real learning, however, is primarily an individual activity and is attained only via an internalizing process.

George Beal (1982) made a distinction between knowledge acquisition, the process of learning facts and new ideas, and knowledge use, the process of learning how those facts and new ideas can be applied in a real-world situation. In knowledge acquisition a person accumulates information. In knowledge use a person learns the skills required to use it and makes judgments about the relative value of information accumulated. He identified the need for a role of "knowledge translator" to be performed to help students relate new knowledge to the context where it will be used.

The experience of distance teaching institutions such as the Open University in the United Kingdom, Athabasca University and the Open Learning Agency in Canada has demonstrated that strong student support is essential to high completion rates (Kaye & Rumble, 1981; Mugridge & Kaufman, 1986)). All of these institutions provide regional tutors for their distance learners. Under the Open University model, the role of the tutor is that of a subject matter expert who provides all assistance related to course content, including "translating" the learning material and marking assignments. The tutorial relationship is essentially one-to-one, and communication between tutor and learner is usually conducted in writing and by telephone.

Under the University of Saskatchewan model, the tutor is a local facilitator who is not expected to be a subject matter expert, but is charged with the responsibility of assisting

groups of learners find the contexts for understanding the information presented by the television instructor, as well as assist the latter in monitoring the learners' progress in integrating the new information. The tutors assume the role of knowledge translators who live in the learners' community and can empathize with many of the learners' experiences and problems. They stimulate dialogue by helping the learners to pose questions, debate different perspectives and seek clarification from the television instructor, the principal knowledge translator.

The Contribution of Local Facilitators to the Learning Environment:

Tutors were hired according to two criteria, relevant academic background and previous experience with adult learners. The criterion of "relevant academic background" varied among different subject matter and was influenced by the academic tradition of particular departments. Both English and History required the tutors to have a master degree in the subject or a cognate area. Because of Saskatchewan's small population and the project's intent to deliver the courses to small rural communities, the administrators experienced difficulty in recruiting enough local tutors with a master degree. A compromise was achieved in the decision to hire "proctors" (with an undergraduate degree) who could lead the local discussions but would not mark assignments. In the latter case, the assignments were sent to the main campus to be marked by the instructor or a campus-based tutor. In the Psychology and Mathematics telecourses, the respective academic departments were more concerned with recruiting tutors who had the practical skills to facilitate problem-solving. Most of these tutors had an undergraduate degree.

From the designers' perspective, the criterion of "previous experience with adult learners" was as important, if not more important than a relevant academic background, given their awareness that one-third to one-half of the target learners were mature students in the 30 and above age range. One of the most highly rated tutors was a farmer with an undergraduate mathematics degree. He was a father of three young children, an organic grain farmer, part-time student, and part-time statistics consultant. Many students credited him with motivating them to "stick with it" as well as helping them with their math. A History proctor was a retired high school teacher whose passion was travelling to the birth places of famous European historical figures. For many years, she had read all she could find on selected notables and places, saved her money over one year, and travelled during her summer holiday. Her love of History was infectious and the students in her region had one of the highest retention rates.

The ability of the local tutors and proctors to understand and empathize with the culture of their students was especially important in the Native Studies telecourse. The content of this course was the result of a collaboration between two departments with somewhat different traditions and student audiences. The latter included both school teachers as well Native learners in a special university access program. The designers were given the information that the Native learners' culture had prepared them for a more process-oriented learning style which included intuitive modes of thought, reflection and silence. It was therefore crucial to hire facilitators who could help these learners translate conventional university learning styles to their own contexts.

At the beginning of each academic year, both tutors and proctors are invited to the Saskatoon campus to participate in a one-day workshop to orient them to the design of the telecourses, to familiarize themselves with their expected roles and functions and administrative procedures, and to be introduced to the studio facilities where the classes will be narrowcast. In their respective group discussions, the instructors of the telecourses stress the importance of the local facilitator's role in stimulating interaction locally as well as on-air during the question period. While they are not expected to be subject matter experts, they have to keep ahead of the students in the reading assignments and provide feedback to the television instructor about how the students perceived and understood his comments and interpretations.

In the pilot year, a survey of the local facilitators was conducted three months after the initiation of the project. The results indicated that while most of them felt that their roles and functions had evolved as they had expected, two tutors expressed personal dissatisfaction with their role as facilitator. Both tutors had previously been hired as off-campus sessional instructors in their communities and appeared to have difficulty adjusting to the "downgrading" of their status. Feedback from the students confirmed that one individual in particular spent the discussion period challenging the television instructor instead of helping the students identify questions and exchange views in relation to the new information presented.

In contrast, proctors and tutors who had no previous experience in teaching university courses expressed personal satisfaction in their contribution to the project in spite of the amount of time they needed to commit to preparing for the course and facilitating the discussion:

> "I am fulfilling my function as proctor exactly in the way that I anticipated when I accepted the position...While they are reading, thinking and writing about a piece of literature, the students use me to check their perceptions. Although I am not able to answer their questions with any real authority, the talking helps. We can bounce ideas off each other and together, are able to come up with some very legitimate interpretations (confirmed by the instructor). My group, and I expect it is typical, is insecure about English and particularly writing. This group has needed a great deal of support, encouragement and my time...I must say I've enjoyed every second of it." (English proctor)

> "A very positive experience...participating in what is a very good idea. The students appreciate the fact that they are getting first class instruction on the same level as students in Saskatoon. They do not get the feeling that they are in some way second class students. I personally find the lectures interesting and informative...Michael (the instructor) lectures very well. He is interesting, well organized, and he gets his material across very well...The reading, preparation and thought that must go into each week's presentation is very considerable...Unfortunately, for me, I must take this time away from my family." (History proctor who signed up for 3 more years)

The local facilitator's contribution to the learning process can be illustrated by the following student comments:

> "I am really enjoying my English class, it truly helps when one has a proctor as helpful and enthusiastic as J.Q."
> "Our tutor puts herself in our shoes...she helps us to understand our questions a lot better...and is helpful on an individual basis."
> "Compared to other classes, it's very important

to have a tutor...Mr. C. is very helpful...without him, I wouldn't have known how to do my assignment on *The Prince*."

Students were also appreciative of the facilitator's help in making calls to the studio during the interactive period with the instructor. During the first few weeks of a telecourse, students usually feel intimidated by the thought of being heard across the whole province. The local tutors and proctors therefore serve as role models in conducting a dialogue ---an exchange of opinions among individuals who achieved different but equally valid interpretations of the lecture and reading assignment content. This exchange quickly expands to include some enthusiastic student callers. A growing concern of the television instructors as the number of learning sites increased is equitable interaction. The English instructor solved the problem by targetting questions to specific receiving sites on a rotation basis. The tutors and proctors of the students who were not on the "hot seat" noted the local reactions and relayed them to the instructor during their staff conference calls. The instructor would then attempt to incorporate these comments in his next lecture and discussion. This strategy was later adopted successfully by both the History and Psychology instructors.

Conclusion:

Our experience with the first four courses has provided our university with some evidence that it is possible to deliver quality instruction to a small, widely dispersed population via a combination of human resources and television and telephone technology. Technology, in this case, served the role of agents of interaction. The task of stimulating interaction at a distance relied primarily on the human resources, the television instructor and the local facilitators, who served as knowledge translators in helping the students find their way through a body of knowledge. To achieve this, the television instructors had to master a variety of television presentational and questioning techniques, while the local facilitators had to learn to unobtrusively encourage students to participate in the interaction. In our experience, the best facilitators are those who have received a thorough orientation to the rationale and design of telecourses and who are personally committed to complementing the television instructor's message with their individual perspectives rather than competing with him as content experts.

As the number of learning sites increased dramatically over the last three years, the recruitment and training of the local facilitators became problematic. The need to respond rapidly to new clusters of rural learners meant that some local facilitators were not hired until after the orientation workshop had been conducted. In spite of the availability of an extensive package of print information, these late comers did have receive the benefit of the television instructor's personal introduction to the course content or the opportunity to establish social affiliation with the course team.

The dual hiring criteria of relevant academic background and experience with adult learners were not met in some cases. To achieve parity of esteem with on-campus courses, the telecourses had to have facilitators with equal or better academic qualifications. Some local facilitators had the appropriate academic credentials, but turned out to be less than ideal in their ability to motivate and facilitate adult learning. In other cases, facilitators who were committed to the principles of adult learning were greatly discouraged by the attitude of some students who wanted to get high marks but were not interested in the discussions.

The University of Saskatchewan model attempts to create a teaching/learning environment that utilizes a team of knowledgeable and caring knowledge translators. In spite of a few unsatisfactory cases, the inclusion of local facilitators as knowledge translators has enhanced the profile of University of Saskatchewan distance education courses in small rural communities, and has contributed significantly to the quality of student support services to our off-campus students.

"The Telecom/Computer Partnership"

William R. Johnson, Jr.
Vice President, Corporate Marketing Planning
Digital Equipment Corporation

Integration is the dominant trend in both the telecom and the computer industries. And integration of these two areas of technology is also a dominant trend. Together, telecommunications and computers are reshaping not only business enterprise but human enterprise. I'd like to address both these forms of integration.

There are three primary change factors causing this integration:
1. technology
2. geo-politics and
3. deregulation.

1. First, technology. In the computer industry, there are dramatic changes in scale:
- entire computer rooms collapse onto the desktop.
- CPU boards collapse to postage-stamp size and smaller.
- product lifecycles spin in what seems like nanoseconds.

In the telecom industry, technology changes challenge conventional thinking about the steps of progress: the fast advance of cellular makes it possible for countries to leapfrog the traditional path to create infrastructure.

2. Second, geo-politics.
- Largely because of telecommunications, the world is shrinking into a global village of interdependencies, especially economic.
- At the same time, nationalism is strong and all countries are striving to use economic development to enhance their world positions and internal standard of living.
- Free markets and privatization are current trends around the world, paving the way for greater opportunity and competition.

3. Third, deregulation. This trend is moving around the globe, from the Americas to Europe and the Pacific Rim. Last year alone, half-a-dozen countries deregulated their phone companies. Much of the telecom industry is expected to be deregulated by the year 2000.

Deregulation means competition on a global scale. It opens the way for companies from around the world to compete for a piece of the infrastructure pie. For example, Mexico's Telmex was sold to a consortium made up of Southwest Bell from the U.S., France Telecom, and Mexico's own Grupo Corso.

These factors - technology, geo-politics, and deregulation - also change the way we do business. The last example illustrates this. Companies from three countries must find a way to work together. So integration is both a technology issue, and a business issue.

On the technology side, all the markets Digital serves are demanding integration -- multivendor integration. Too much money has been invested -- trillions of dollars, in U.S. terms -- to justify any other approach. Integration is important in telecom principally because the networks that serve as backbones have grown rapidly in size and complexity. Worldwide infrastructures have been deployed over several years using a wide variety of technologies.

Now, especially because of increased competition, there is a need to improve service, reliability, and cost structures. One important way to achieve these improvements is by integrating disparate networks and systems into a unified entity that can be managed more successfully and efficiently.

This form of multivendor integration is critical to the telecom industry's development, but it is a tough nut to crack. We know. We're cracking it.

One result of our work with telecom providers is Digital's Enterprise Management Architecture for multivendor telecommunications networks. EMA utilizes industry and international standards to integrate network management and create an open development environment.

In fact, industry and international standards are central to our entire product strategy. This is because the direction of the industry -- the direction of all industries utilizing information technology -- dictates multivendor integration.

Our business focuses so strongly on multivendor integration that we launched The Open Advantage campaign to clarify within the marketplace the full scope of integration and openness. Judging from our growing experience in delivering multivendor integration, it takes more than UNIX or a few standard interfaces.

Multivendor integration takes a whole open business approach, which means providing open technology, but just as important, it also means your business practices and the service and support you provide.

I want to say a few words about this idea of an open business approach, because, although I am a marketing executive, this is more than just a marketing slogan. In fact, of all the profound change occurring in our industries, the idea of an open business approach is every bit as radical as the change in technology.

The reason I say "radical" stems from what I call the 3-C model, which says that at any given moment any number of companies will be your customers, your competitors, your collaborators. Not just one of these, but all three.

For example, IBM is a long-standing competitor of ours, but we also buy each other's products - so we are customers - and we serve together on many industry consortia as collaborators.

Many of you already are seeing this happen for your companies. The Mexican phone system example illustrates this again -- competing phone service providers are collaborators on an ongoing basis.

These really are profound changes. When you are used to competing hard against a company, it takes real effort and genuine motivation to collaborate. And it isn't easy to have a trusting relationship with a customer who is also your competitor. But this is what it is going to take to compete and serve in the world markets of the 1990s and beyond.

Many partnerships and alliances already exist, crossing international as well as industry borders:

- Motorola is providing cellular services to Indonesia.
- British Telecom is going to build and operate Thailand's telephone network.
- Taiwan and Bell Atlantic are exploring worldwide joint ventures.
- And Ameritech and Bell Atlantic purchased New Zealand Telecom.

These companies and governments are recognizing they are part of a global economy, with tremendous opportunities arising from changes in technology, geo-politics, and the regulatory environment.

What does it take to operate in a world that exists on a dichotomy between global and local concerns? It takes an organizational approach that is at once global and local. This translates into two further dichotomies -- the successful company of this decade must also be both big and small and decentralized yet disciplined.

What does this mean? - It means that customers and markets must be approached from a local perspective to deliver products and services that really do something for people in their own cultural context. At the same time, resource management must be global to find the very best design and manufacture, as examples, at the very lowest prices...wherever they exist.

- It means that a company must operate with the agility, entrepreneurism, and speed of a small company, but with the resources of a large company.
- It means that a global company must operate with the autonomy and customer focus of a decentralized company while exercising the corporate discipline of a hierarchical company.

The organization needed to compete in today's world is more than flexible -- it is elastic. Even its external borders change as it expands to include partnerships and alliances enabling it to be both large and small, global and local, decentralized yet disciplined.

The competitive structure for today and beyond is the dynamic organization. We've reached the stage where computers are not just essential to business operations, they are fundamental. Computer networking is the foundation for elastic, dynamic operations.

And the telecom industry ... together with the computer industry ... are the central providers of this very important capability.

Within an enterprise, networking is the means to balance between global and local, decentralized and hierarchical, large and small. Networking further serves to enable an enterprise to extend its borders to include partners, customers, researchers, and other important collaborators.

This is how we at Digital operate, as we have for many years. We sell what we live to our customers, helping them reshape their businesses. And together with our customers and our partners in telecom, we are helping to reshape human enterprise.

* For example, the integration of Germany is happening with the rapid deployment of a nationwide cellular phone system.
* The privatization of Czechoslovakia's economy will be helped by the creation of a network infrastructure.
* In medicine, online images of x-rays will enable doctors in rural areas to consult with specialists in cities, improving healthcare for large numbers of people.
* The government of South Australia plans to develop a state-wide information utility. Their partners in the program include both Digital and a competitor plus two competing telecom companies.

Its purpose is to integrate voice, data, and radio communications to serve government, the public, private business, and education.

South Australia intends to use this information utility to become more competitive in the world market and to help develop its own people and their standard of living.

Partnership is at the heart of the best changes taking place in our world today. The partnership of telecom and computers offers possibilities we might not have dreamed of...just a few years ago.

Together we can make the world a better place.

Asia Pacific Economic Cooperation (APEC): A Forum for the Future

Ambassador Bradley P. Holmes
U.S. Coordinator and Director
Bureau of International Communications and Information Policy
U.S. Department of State
Washington, D.C., United States

Abstract

Since its inception, the Asia Pacific Economic Cooperation (APEC) initiative has made great progress in telecommunications within a region which continues to change socially, technologically, and economically.

I. Introduction

It is a pleasure for me to come before the Pacific Telecommunications Council again to discuss the flourishing Asia-Pacific region and, in particular the Asia Pacific Economic Cooperation, commonly referred to as APEC. APEC is a relatively new economic and political framework in the Asia Pacific area intended to encourage increased economic cooperation and consultation, promote trade and investment flows, and help strengthen the multilateral trading system.

Today, I am glad to report that APEC is fulfilling its promise that I spoke of last year at PTC'91. Since its inception, the APEC initiative has made great progress within a region which continues to change socially, technologically, and economically. In particular, APEC is focussing on the regional telecommunications environment and is taking great steps to further telecommunications development.

II. APEC Background

APEC was established to deal with the effects of growing interdependence within the Pacific arena. A new mechanism for multilateral cooperation among the Asia-Pacific market-oriented economies clearly was needed. APEC is just the mechanism to fill that void. APEC began with 12 countries, and has become crucial in sustaining market-oriented growth, advancing global and regional trade liberalization, and meeting the new challenges of interdependence.

At the recent APEC Ministerial in November, the Ministers welcomed the participation of the People's Republic of China, Hong Kong and Taiwan in APEC. The participation of these three important economies will greatly contribute to economic growth and dynamism while increasing the potential for APEC to become a major political force in the Pacific arena.

Each of these three dynamic economies is undergoing different stages of economic restructuring to address the demands of a highly competitive, global marketplace. These changes are evident in telecommunications, where each economy is at a different stage of development. Hong Kong has a developed, open, competitive and liberalized environment. Taiwan plans to improve their telecommunications infrastructure through their six-year development plan, and is currently revising its telecommunications law to make more telecommunication services available through the introduction of a competitive environment. China is in its early stages of development in a wide variety of sectors, with telecommunications being central to its overall development process. By bringing unique experiences and perspectives to the table, these three economies will add tremendous value to the APEC process.

The Asia Pacific region has become America's largest trading partner. America's trans-Pacific commerce is now more than $300 billion in annual two-way trade - nearly one third larger than that across the Atlantic. The United States exports more to Thailand than to Ireland, more to Indonesia than to central and eastern Europe and more to Singapore than to Spain or Italy. Moreover, U.S firms have invested more than $61 billion in this area, with over $95 billion of Asian investments in the U.S.

Secretary Baker recently drew an analogy between the Pacific area in the 21st-century and the development of the American continent in the nineteenth-century. He said, "As the pattern of expansion and influence in the American West was determined by the location of telegraph and railroads, so the infrastructural links we are building across the Pacific in areas such as telecommunications and transportation will shape the economic and political character of the region and our ties to it."

This analogy is especially illustrative, because it exemplifies not only the exciting and rapid economic development in this area, but it emphasizes the importance of telecommunications in the overall development of any country or region.

Telecommunications has increasingly acquired major strategic political, economic, and social importance in the Asia Pacific area. It has become essential in most countries as a basis for improving economic infrastructural efficiency while expanding participation in global markets. For many firms in this region — both in manufacturing and service sectors — telecommunications has become a tool to enhance competitiveness by providing instant communications and a network of business relations.

The increasing globalization of markets, served from world-wide sources through new telecommunications infrastructures and services, will continue to reshape the fifteen participating APEC economies over the next decade.

For these reasons, the U.S. promoted the creation of the Working Group on Telecommunications and the second APEC Senior Officials Meeting in Singapore, May 1990, agreed to add telecommunications as its seventh project. The Working Group on Telecommunications was organized, with the U.S. as its shepherd, and held its first meeting in Singapore in July 1990.

This Working Group is the first broad, regional organization of governments from the Pacific Rim that brings government and private sector officials from both sides of the Pacific together to examine important telecommunications issues.

I would like to bring you up to date on APEC's recent accomplishments, the outcome of the APEC Ministerial in November, as well as APEC's activities in telecommunications.

III. APEC Ministerial

In the spirit of regional cooperation and economic growth, the APEC Ministers held productive discussions during the Seoul Ministerial on a wide range of topics including regional economic trends and issues, the Uruguay Round and trade liberalization, the APEC work program and future plans.

Although their primary focus was the successful conclusion of the Uruguay Round, one of the most important accomplishments was the declaration of APEC's principles and objectives. This Declaration gives APEC a distinct international agenda, states APEC's aims, and provides a firm foundation on which to base APEC's work for the years to come.

In their declaration, the APEC ministers recognized that the dynamic growth of economies brings growing economic interdependence, and that closer cooperation is needed to effectively utilize human and natural resources to attain sustainable economic growth and reduce economic disparities.

The APEC Ministers declared that the key objectives of APEC are to maintain the growth and development of the region, to enhance the benefits from increased economic interdependence, to develop and strengthen the open multilateral trading system, and to reduce barriers to trade and investment among APEC participants.

IV. Work Program

By taking a far-reaching and comprehensive approach in designing its progressive work program, APEC incorporates many different industries and facets of the economy. In fact, three additional work projects in fisheries, transportation, and tourism were recently adopted thereby expanding the work program to ten working groups.

These working groups are committed to open dialogue and consensus building taking into account the different stages of economic development among their members. They draw upon research, analysis and policy ideas from participating economies and other organizations such as the Association of South-East Asian Nations (ASEAN), the South Pacific Forum (SPF) Secretaries, and the Pacific Economic Cooperation Conference (PECC).

In addition, the private sector plays a critical role in APEC. APEC is not only a cooperative effort among its member countries, but it also requires close consultation between government and the private sector. The private sector is vital to the success of APEC, and is encouraged to participate.

In each of the ten areas, the APEC Working Groups seek:

1. to identify and define the region's common interests and project these interests in multilateral forums such as the GATT;
2. to promote consistency in policy making when appropriate by better understanding the policy concerns, interests and experiences of economic partners;
3. to develop practical programs of economic cooperation and to contribute to economic dynamism; and,
4. to promote the role of the private sector and the application of free market principles.

As an example of how the working groups are meeting these objectives, the Trade Promotion Working Group is establishing the APEC Electronic information Network (APEC ELIN) which connects Singapore's TDB Globalink with computer systems of each APEC member to exchange trade and industrial information. The Working Group on the Expansion of Investment and Technology Transfer in the Asia-Pacific Region has finalized a manual and inventory to assist in creating and managing technoparks.

The Regional Energy Cooperation Working Group collected energy supply and demand data from APEC members to form an energy database. They will study the potential use of clean coal technology and consider creating an APEC Coal Utilization Center for developing and introducing these technologies.
In the newly established Working Group on Fisheries, specific work plans are underway to identify fish stocks with management problems that require international cooperation; to cooperate in fish harvesting and post-harvesting technologies, and to cooperate in product marketing.

These are just a few of the examples. Activities that are equally as impressive are underway in the working groups that focus on transportation, trade and investment data, human resource development, investment and technology transfer, marine pollution, and telecommunications.

V. Working Group on Telecommunications

The Working Group on Telecommunications has taken a broad and comprehensive approach to promoting telecommunications that meets APEC's objectives of identifying common interests and policy concerns; promoting consistency in policy making; developing practical programs to contribute to economic dynamism; and, promoting the role of the private sector and the application of free market principles.

By working together to establish practical applications for telecommunications development, this working group is gaining a high level of understanding of the region's current technical environment. Under the leadership of Indonesia, Korea, and the U.S., the Working Group developed a detailed questionnaire for the APEC members to complete. The Working Group compiled data regarding the policy, regulatory, and network environments for each APEC participant. Korea kindly published the results for the November Ministerial.

This compilation provides a ready source for broadening our awareness of the telecommunications environment among APEC economies. It also provides a basis for developing specific recommendations for the Minsters' to consider when developing their telecommunications infrastructure and introducing new techologies. With this comprehensive survey, APEC will assess this year the rules regarding foreign investment in telecommunications, the standards setting process, and the relevant national laws and regulations. The Working Group plans to update these reports on an annual basis, thus providing a continual foundation for ministerial recommendations.

Japan, as one of the project rapporteurs for network development, proposed that the Working Group undertake a study on teleports in an effort to promote high quality international telecommunication networks in this region. This study identified issues that the Working Group should address when considering teleports as a means of enhancing the telecommunications infrastructure.

The Working Group held a seminar on teleports in May 1991 in cooperation with PECC to increase its awareness of teleports. This year APEC will continue to study teleports and its potential benefits. In particular, they will establish a better definition of teleports, design a work program, and get a better understanding of the needs of teleport users, management and financial issues, and regulatory effects.

Although the Working Group emphasizes network development, it has not lost sight of the human element of telecommunications. APEC acknowledges also that education is essential to the success of telecommunications operations across the board, not just in EDI. This Working Group is creating a manual entitled, "How to Approach Training Within A Telecommunication Organization" for meeting future human resource needs. The participants are

aggressively working on the manual, and they expect to present it this year at the September APEC Ministerial in Bangkok. Once the manual is completed, the Working Group will consider pilot testing the suggested recommendations and procedures in the manual by inviting telecommunications administrations to field test their recommendations.

The Working Group realizes also the far reaching impact of telecommunications applications, like Electronic Data Interchange, EDI, and has initiated a project to incorporate EDI into the regional trading arena.

Since effective international trade requires fast, efficient and accurate information to ensure the smooth flow of goods and services, the adoption of EDI throughout the Asia-Pacific region will generally enhance the facilitation of international trade within APEC countries and with other parts of the world. This EDI project could lead to the total electronic exchange of trade documents among APEC economies by the end of the decade.
Under this concept, APEC members are encouraged to actively develop international EDI applications in government to government, trade to government, and trade to trade transactions within their area. The U.S. is taking the lead in this effort, and we expect these plans will fall into place this year.

Initially the Working Group will develop pilot projects between interested members. However, the ultimate aim is to involve all APEC members. The results of the pilot projects will be shared among all members to demonstrate the operation and benefit of EDI.
To complement the implementation of the pilot projects, the Working Group accepted the EDI Council of Australia's proposal to develop a comprehensive education awareness program tailored to meet the specific needs of APEC members. This program will increase the awareness of EDI and its benefits throughout the region.

VI. Future of APEC

This year will be an important one in the evolution of APEC. Not only will APEC address key administrative issues such as the creation of a secretariat and the financing of projects, it will also work hard to integrate the newest members of the APEC family - China, Hong Kong, and Taiwan - into its process.

As for the future of telecommunications in APEC, I contend that as it broadens and continues to mature, telecommunications will retain its cornerstone position. This paramount position within APEC fulfills the promise of such groups as the PTC while making APEC unique among multifunctional, regional economic initiatives.

However, the importance of APEC is more than just the discrete projects that the working groups are pursuing or the individual economies that belong. It is, in fact, a true case where the sum of the parts is indeed greater than the whole. The mission of APEC is to be a truly cooperative effort that should produce real economic benefits for the entire region. Private sector is certainly welcome to join in this initiative as APEC embarks upon this year of implementation and cooperation.

Tuesday, January 14, 1992

Plenary

NOTES

INTELSAT SERVICES: COMMUNICATIONS FOR THE WORLD

David T. Tudge
INTELSAT
Washington, D.C. U.S.A.

1. Abstract

INTELSAT serves the world with a comprehensive system of satellites and services. The quality and availability of INTELSAT services have increased, while costs have declined significantly. The burgeoning demand for global telecommunication services has taken up most of existing INTELSAT capacity, requiring additional capacity for future growth. The Pacific Ocean Region has unique service requirements and has experienced growth in all service areas. INTELSAT is planning how best to meet the needs of users in the Pacific Ocean Region and the other ocean regions, now and into the 21st century.

2. OVERVIEW OF THE INTELSAT SYSTEM

The INTELSAT system is a comprehensive and reliable global telecommunication network, with the largest commercial spacecraft fleet of any organization in the world. With the successful launch and deployment of the last two INTELSAT VI satellites in 1991, the INTELSAT system now has seventeen spacecraft in orbit available for service. This is the largest number of satellites in service in INTELSAT's history, and all are being utilized to meet the ever growing service requirements of INTELSAT's 180 user countries, territories, and dependencies.

The INTELSAT fleet today comprises four INTELSAT VI spacecraft and thirteen INTELSAT V and V-A spacecraft. Pacific Ocean Region users are served by four INTELSAT V/V-A satellites. Many Pacific users also utilize INTELSAT spacecraft in the Indian and Atlantic Ocean Regions, but for those Pacific nations with small amounts of traffic, the Pacific Ocean satellites are their primary source for international telecommunication services.

3. SCOPE AND PRICE OF SERVICES

Demand for INTELSAT services continues to grow in spite of competition from fiber optic cables and separate satellite systems. At the end of 1991, INTELSAT carried close to 125,000 full-time channels for voice and data and over 150 full-time leases for video, domestic, and business service applications. About one-third of our members use INTELSAT capacity to meet their domestic requirements, as well as their international requirements, and domestic lease services represent the largest percentage of full-time leases, system-wide, followed by international video leases. In addition, there has been dramatic interest and significant growth in transportable VSAT services.

INTELSAT's service priorities have been directed towards fostering network flexibility, both in space and on the ground, and developing less expensive and more efficient offerings to help members compete in an increasingly deregulated environment. INTELSAT has consistently offered more and better services, as reflected in the magnitude and scope of use of its resources, while steadily increasing system efficiency. In 1970, INTELSAT carried less than 5,000 full-time channels and no domestic service. Over the past ten years, full-time system use has more than doubled and full-time lease services have increased almost ten-fold. Throughout INTELSAT's history, it has consistently effected major reductions in the cost of service. For example, the cost of a voice channel has declined in real terms over a hundredfold since INTELSAT provided the world's first commercial telecommunication satellite voice channel, and a voice channel can now be obtained for as little as a U.S. dollar per day. This productivity has been achieved through technological innovation, the economies of scale made possible by ever increasing usage and system growth, and strategically pricing and marketing services. But INTELSAT has eschewed cross subsidy and expects to compete in price terms on a fair basis.

INTELSAT has aggressively pursued several initiatives over the past few years the cumulative impact of which has been extremely cost-effective communications. These initiatives include financial incentives for efficient use of space segment resources and conversion to digital operation and significant discounts for long-term commitments to system use. These kinds of initiatives will sustain INTELSAT in the years ahead and help the Organization to enhance its own and its users' competitive advantage, while attracting a growing level of traffic to the system.

4. ACCESSIBILITY

Aside from the price being right for INTELSAT service, the INTELSAT system has become easier to use. This goal has been accomplished in several ways. More options are available for users to acquire bulk capacity and configure it however they wish to best meet their needs. For example, INTELSAT now offers a transponder for unrestricted use service which permits users to acquire and use bulk capacity allotments for whatever international, regional, or domestic communications they wish. Ground network configurations are far more flexible and user specific, and INTELSAT's structure can accommodate a variety of access arrangements to meet individual country requirements as deregulation and privatization initiatives are undertaken.

4. 1 USE OF SMALL ANTENNAS

If ISDN was the buzzword of the 1980s, VSAT is the buzzword of the 1990s. As the INTELSAT space segment has evolved to more powerful and flexible operation, ground network options have also expanded. From the introduction of the INTELSAT Standard B antenna in 1976 to facilitate system access by users with smaller traffic requirements, INTELSAT earth station standards have evolved to keep pace with user requirements for more cost-effective and customer responsive network solutions. Today, given INTELSAT's many service options, the array of earth station choices is almost limitless. Earth station antenna sizes can range from the 15-18 meter size of a Standard A to under 2 meters for some business and video applications. Indeed, transportable VSAT services is one of INTELSAT's primary areas of growth, and as such, they are a top priority for INTELSAT.

INTELSAT has taken a number of steps over the past few years to extend the range of service options available with small antennas. Among these are INTELSAT's television broadcast services, INTELSAT Business Service, Intelnet, and even IDR service, where earth station antennas as small as 4.5 meters can be utilized. Domestic lease services also have the flexibility to accommodate any type of earth station configuration the user desires.

Satellite News Gathering (SNG) as a form of video broadcasting via transportable antennas is one of INTELSAT's fastest growing services and, indeed, of the international television business as a whole. Currently 21 Signatories have registered over 184 transportable earth stations for operation on the INTELSAT system to provide instant news coverage worldwide. SNG is now a day-to-day method of transmission within the INTELSAT system. This technique has become invaluable for coverage of world news and special events, such as the crisis in the Persian Gulf and the attempted Moscow coup in 1991. It was also used during the transmission of the Asian Games from the People's Republic of China in 1990 and will be used extensively during the upcoming Olympic Games in France and Spain in 1992.

Among INTELSAT's VSAT offerings, Intelnet is one of the most flexible. Intelnet networks use small, customer-premise earth stations, providing interactive service on terminals as small as 1.2 meters in diameter. Receive-only services are available on the smallest terminals that are on the market today. Because Intelnet can be used with such small earth stations, it can be implemented at very low cost and with considerable flexibility for expansion. One example of current applications of Intelnet is the Reuters News Service, which operates to over 1,000 receive-only terminals worldwide from its home office in London. Another example is Hong Kong International's World Broadcast Service which enables a subscriber to deliver data, pictures, facsimile and a teleprinter signal simultaneously and at different speeds.

Additional VSAT services are an important focus for INTELSAT in future service offerings and spacecraft designs. For example, INTELSAT is actively exploring and developing a C-band microterminal offering using very small, 0.5 to 1 meter terminals. Actions now underway include design and specification of both the hardware and the software for such a microterminal and related hub equipment. These terminals would be operated as part of a demand-assigned network of shared hubs providing two-way voice and data. A number of different applications could be supported by such an antenna, from thin-route telephony for rural and remote telecommunications to auxiliary voice channels for SNG operations. These C-band microterminals will be designed to operate with both global beam transponders for maximum worldwide coverage, as well as with any INTELSAT leased capacity to augment existing domestic or regional networks.

4. 2 MULTIPLE ACCESS

In addition to service and operational flexibility, INTELSAT's structure has sufficient flexibility to adapt to a changing environment where

privatization and deregulation promote multiple service providers. There is nothing in the INTELSAT Agreements which prevents INTELSAT from dealing with more than one carrier in a country. The Operating Agreement does impose specific requirements on a Signatory, but these do not prevent conclusion of arrangements that permit non-Signatory entities to deal directly with INTELSAT. A very wide variety of arrangements has been put in place to meet the diverse requirements of different member countries.

INTELSAT can accommodate the wishes of each country to fit the domestic regulatory regime of that country, particularly as those regimes change to reflect increasing deregulation, competition and privatization. For example, in the region Australia, New Zealand, and Korea have adopted multiple access arrangements, and other INTELSAT member countries are considering it. Activities which have already been accommodated under the Agreements with the approval of the Signatory concerned include: direct submission of earth station applications; direct discussion of services and tariffs; direct booking of leases and allotments; direct billing; direct payment; direct receipt of INTELSAT documents; attendance at INTELSAT meetings; and investment in INTELSAT through the Signatory's investment share. Any or all of these activities can be tailored to fit a member's particular domestic regulatory requirements.

5. FUTURE CAPACITY PLANS

With better quality, unmatched reliability, service flexibility, and decreasing costs, it should come as no surprise that demand for INTELSAT services is experiencing healthy growth system-wide. While overall traffic totals in the Pacific Ocean Region are not at the same levels as in the Atlantic and Indian Ocean Regions, Pacific basin service demand is outpacing growth in the other two regions in both the nearer and longer term. System-wide, INTELSAT anticipates a shift in demand patterns through the end of the century, as public switched network telephony traffic is divided between fiber optic cable and satellite and demand for video, domestic, and regional services grows. This trend is reflected in traffic forecasts for the Pacific Ocean Region which indicate that the greatest growth is anticipated in video, domestic, and business service applications. INTELSAT must take these factors, as well as varying requirements among ocean regions, into account when planning how best to meet future needs.

5. 1 PACIFIC OCEAN REGION GROWTH

As of the end of 1991, the four satellites serving the Pacific Ocean Region carried more than 20,000 full-time channels and 31 full-time leases, the majority of which were for video service. The most recent INTELSAT traffic projections, provided by Pacific Ocean Region users to INTELSAT's 1991 Global Traffic Meeting, indicate that Pacific Ocean traffic will experience very healthy growth through the remainder of the century. Pacific public switched telephony is forecast to experience modest growth over the next five years, a total of about nine percent between 1991 and 1995, and more significant growth over the next ten years, more than a third of 1991 totals, in spite of the proliferation of fiber optic cables in the Pacific. Anticipated growth in full-time leased services is far more impressive, particularly when one considers that the level of service in the Pacific in the near term is constrained by the lack of available capacity. The rate of growth in full-time leases is forecast to increase by more than two-thirds over the next five years and to more than double over the next ten years. Based on the traffic forecasts, video remains the lease service most in demand.

5. 2 OPPORTUNITIES FOR REGIONAL AND DOMESTIC NETWORKS

While video is an important service for the Pacific Ocean Region, regional, domestic, and business services are likely to become more important in the future, as additional capacity becomes available and as the region as a whole continues to experience a synergistic growth and economic development. Currently, several Pacific basin nations utilize INTELSAT capacity for domestic service, albeit primarily on Indian Ocean Region satellites at the moment: China, Japan, Malaysia, and Thailand. The Asia-Pacific Broadcasting Union has developed a regional video distribution network using INTELSAT's multiple origination/destination television service to facilitate news exchange among several Asia-Pacific nations.

Several Pacific Ocean nations are already using INTELSAT Business Service (IBS) to implement regional and international business networks. For example, our Malaysian Signatory, Syarikat Telekom Malaysia Berhad, is using IBS to link several electronics manufacturing companies with sites in Malaysia to their headquarters locations in the United States. Japan's Signatory, Kokusai Denshin Denwa Company Ltd., offers a high-speed business communications service know

as HI-BITLINK using IBS. Singapore's Signatory, Singapore Telecom, has an innovative digital videoconferencing service that it introduced in 1988, demand for which continues to increase.

The opportunity to enhance and extend domestic, business, and regional networks for Pacific basin users will increase when new capacity becomes available with deployment of the first INTELSAT VII spacecraft in 1993.

5. 3 LOCATIONS AND TIMING OF FUTURE INTELSAT SPACECRAFT

Current INTELSAT planning for the Pacific Ocean Region maintains a four-satellite configuration throughout the end of the century, two station-kept satellites at the 174°E and 177°E locations and two satellites in inclined orbit operation at the 180°E and 183°E locations. Current INTELSAT planning assumes launch and deployment of the first two INTELSAT VII satellites in the Pacific Ocean Region at the 174°E and the 177°E locations in fourth quarter 1993 and first quarter 1994.

The INTELSAT VII series was designed and developed for flexibility to meet the unique requirements of each ocean region, using the special requirements of the Pacific Ocean Region as the prototype. The INTELSAT VII spacecraft have several features that can be tailored for Pacific Ocean requirements. These include higher power at both C- and Ku-bands; wideband digital transmission capabilities, particularly at Ku-band to satisfy expanding business service needs; reconfigurable antenna coverage to respond to shifting traffic patterns; and improved connectivity.

INTELSAT VII satellites will provide more useable capacity than the INTELSAT V and V-A satellites they will replace. This is the result of the availability of more transponders (36 for the VIIs compared with 32 for the Vs), more bandwidth (2432 Mhz instead of 2250 MHz), and more power, combined with design features for more efficient use. Thus, each INTELSAT VII will have an average capacity of 18,000 simultaneous two-way telephone circuits, plus three TV channels, with the potential for up to 90,000 two-way circuits using digital circuit multiplication equipment. The e.i.r.p. levels of the INTELSAT VII satellites have been developed for compatibility with small earth station operation at both C- and Ku-band (33 dBW at C-band and an average of 46 dBW at Ku-band). These satellites will also provide more flexibility since they have steerable C-band antennas which can be adapted and configured for international and domestic requirements. They also have three Ku-band spot beams which are fully and independently steerable. A total of ten transponders is selectively assignable among the three spot beams to provide a flexibility not achievable previously on INTELSAT satellites.

A special session on the INTELSAT VII spacecraft has been organized and will be held during PTC for those interested in more details on the satellite's operation and capabilities.

6. CONCLUSION

Growth in service demand in the Pacific Ocean Region has given and will continue to give INTELSAT a special challenge. The diversity of needs requires a distinctive solution. INTELSAT has developed a dynamic and responsive solution for Pacific Ocean communications with INTELSAT VII satellites. System alternatives under consideration will extend and enhance the service flexibility required by Pacific Ocean users. INTELSAT, both now and in the future, will adapt to serve the world's changing telecommunication needs, reliably and effectively.

Pacific Technology Growth

William B. Carter
International Facilities Management
and Submarine Systems/SBU
Morristown, United States

The growth in technology of undersea communications will provide capacities undreamed of only a decade ago. It will permit international communications services - voice, data, and image, that which we have not yet been able to imagine.

Technology has had a significant impact on communications all over the world. The Pacific basin, with its large area of water to cover, has benefited more than any other from the advancement of technology.

As each new cable was placed in service, the demand for communication services was increased. As each Administration placed these advances in their networks, our customers have taken advantage of the faster and larger capacity offered.

Changes in submarine cable technology has been even more significant than one would have believed in 1964.

In 1964 when the first submarine cable (HAW-2/TPC-1) was laid across the Pacific (AT&T - SD type), the capacity offered was 143 voice grade circuits between AT&T (then the only U.S. carrier) and its Pacific Basin partners.

Going from vacuum tube technology (AT&T SB Cable) to the transistor technology, the AT&T SD Cable was out in the forefront of submarine cable technology. The latest TPC-3 and TPC-4 Cables use fiber and light rather than copper and electrical signals as a transmission medium.

By the year 1974, total cable capacity was around 1,000 voice grade circuits.

The introduction and provisioning of digital submarine fiber optic cable facilities have been rapidly expanding in the Pacific. Starting with the first digital fiber optic cable, HAW-4/TPC-3 in April 1989, additional fiber optic cables have already been installed (G-P-T, H-J-K, HONTAI-2 NPC) and additional fiber optic cables are planned. On an average, approximately 13,000 Km of submarine cable is being constructed in the Pacific every year.

Although ocean spanning fiberguide cables are not yet three years old, undersea digital technology already directly connects over 20 countries in the Western Pacific, North America and Europe, and additional systems currently planned will nearly double that number. New optical amplifier technology now under development for application in the middle of this decade will provide bandwidths undreamed of only a decade ago.

The first generation of high speed digital fiberguide systems began providing service across the Atlantic as TAT-8 in 1988 and the Pacific as Hawaii-4/TPC-3 in 1989. These 280 Megabits per second 1.3 micron systems gave digital connectivity over cable between Japan, the United States, France, and the United Kingdom. They provide capacity of 40,000 voice circuits, much greater than that of the last generation of coaxial systems with cable size and repeater spacing approaching that of the earliest coaxial designs. The transmission performance, such as errored seconds, by far exceed owners' specifications. The transmission performance is rated by the end user as excellent.

Systems currently under manufacture and installation have continued the rapid technology advance. These second generation systems operate at a 1.5 micron wavelength, the so-called third transmission window. Lasers which emit only a single frequency of light are used instead of the multi-frequency lasers of the first generation systems. Repeater spacings are now up to 150 kilometers. The transmission rate is 560 Megabits per second and total capacity is up to 120,000 voice circuits. This technology will be employed to extend digital connectivity over cable to Australia, New Zealand, Egypt, India and other nations. It will also be used in TAT-9, TAT-10, TAT-11, Hawaii-5 and TPC-4 to supplement the initial ocean spanning cables. It is expected that the number of kilometers of second generation systems will far exceed that of the first. Soon hardly a corner of the earth will lack the benefits of the quality digital connectivity provided by cable.

The latest planned submarine fiber optic cable technology involves AT&T/KDD Bell Laboratories Optical Amplifiers rather than Regenerative Repeaters to amplify the digital signals. This "OA" (optical amplifier) technology allows for significant increases in cable capacity and is the first time that a cable's capacity will far exceed the capacity of a satellite.

Optical amplifiers will lead to repeaters that are significantly less complex than those required for the first and second generation undersea systems. The transmission path in the repeater will consist only of the erbium doped fiber and some optical filters and couplers. The critical optical component is the laser pump. This device, however, will need to operate only as a continuous source of photons in contrast to the laser transmitter in the

regenerative systems where the spectral characteristics of the light are critical. Consequently, achieving suitable reliability for the laser in an amplifier system should be a less challenging task.

Already various laboratories have demonstrated transmission of at least 10 Gigabits per second over distances greater than 10,000 kilometers. These experiments use a recirculating loop in which an optical pulse stream is launched into a closed loop of several fiber spans and amplifiers. The pulses propagate many times around this closed configuration to simulate ocean spanning distances. Also, direct non-loop experiments have been successfully performed at Gigabit rates over a few thousand kilometers and it is expected that a direct experiment of 9,000 kilometers will be performed within a few months. Initial application of optical amplifier based third generation systems in the Pacific and the Atlantic is planned for 1995.

Locations currently served by digital fiber optics cables include:

Hawaii	Hong Kong
Guam	Japan
Korea	Philippines
Taiwan	United States

New digital cables are bing added each year, such that by the end of 1994, eight new locations will have joined the growing Pacific network.

Australia	Malaysia
Brunei	New Zealand
China	Singapore
Indonesia	Thailand

Some of the Locations will have more than one cable (Path) terminating on their shores, thereby being able to offer diversity to you, the customer. These new countries are:

Australia	Malaysia	Thailand
Japan	Taiwan	Indonesia
Singapore	Hong Kong	Philippines
Brunei	New Zealand	USA

Restoration of existing cables and cables planned for service in the early 1990s have depended on using a combination of satellite capacity and unactivated capacity on the most recently installed cable. There are several problems with this arrangement:

Satellite restoration provides rather small capacity as compared with the capacity of the TPC-5 CABLE NETWORK and requires dedicated Earth Station equipments/access facilities.

Cable restoration capacity is constantly decreasing as more DS-3 facilities are activated for service.

Cable on cable restoration between separate cable systems requires complex interconnecting arrangements and agreement between the Management Committees of the involved cable systems and, in some cases, requires dedicated terrestrial equipment and access facilities.

Starting in 1994 and continuing through 1996, a new series of Optical Amplified, high capacity digital fiber optic cables will be installed in a "LOOP" connecting the western United States to the Pacific community, via Hawaii-Guam to Japan and back to the United States.

Known as the TPC-5 NETWORK, this new system will provide much needed additional trans Pacific capacity that will feature diversity, reliability and a dedicated restoration fiber pair. This dedicated fiber pair will be used for extremely rapid fiber-to-fiber restoration in the event of a cable failure.

The capacity available on the TPC-5 NETWORK will be 120,480 64Kb circuits.

As I stated earlier, with the 1964 introduction of the TPC-1 Cable, there were 143 circuits available. The TPC-5 Network will offer a band width having the capacity of offering 120,480 64Kb circuits. We are proud of AT&T and KDD Laboratories for developing the Optical Amplifier. Thereby giving us the opportunity to offer you the type of capacity that enables you to meet your varied and constantly increasing communication needs.

Telecommunications entities internal and external to the Pacific have made enormous investments to provide all of these.

By year end 1998, the International Common Carrier will have invested in excess of four billion dollars in Pacific Basin Submarine Fiber Optic Cable Systems to meet the needs of our customers.

This new technology will be one more step in the long and glorious history of undersea communications, digital transmission and photonics. It will provide capacities undreamed of only a decade ago at a cost also undreamed of only ten years ago. It will permit international communications services - voice, data and image - that we have not yet been able to imagine.

TELECOMMUNICATIONS IN DEVELOPING COUNTRIES - BENEFITING FROM NEW TECHNOLOGIES

M.V. Pitke
Tata Institute of Fundamental Research
Homi Bhabha Road, Bombay 400005, India

1. ABSTRACT

Recent advances in technology have brought down considerably the cost of transmission and switching hardware. The emerging intelligent network technology provides further possibilities of reduction in investment for the new expanding networks. A judicious application can result in very significant cost savings.

2. INTRODUCTION

Recent advances in solid state electronics, digital signal processing and software development and management techniques has significantly brought down the cost of transmission and switching components of a telecommunication network. Although there is considerable scope for reducing the average investment for providing one telephone line, in practice there is no significant impact as yet. One of the reasons for this is the continuation of the traditiona. ways in which telecommunication plans get implemented. Our studies indicate that by adopting a new strategy, it may be possible to reduce the level of investment per line from 30% to 50% of the present levels. In order to be able to achieve this, a three pronged approach is required. Technology, topology and operations are three most important factors. A set of digital switching and transmission products well matched to the countries' needs is perhaps the single most important factor in effecting economy. The next important factor is the network topology that will take into account the powerful signalling and information networking capabilities that are now provided by even the smallest switches. Use of remote maintenance unattended operation, graphics-oriented network management and control tools help further in bringing down the overall investment.

3. TECHNOLOGY OPTIONS

Following are the technology components that are of immediate relevance:

- Optical fibres
- Digital microwave
- Digital crossconnects
- Digital/cellular radio
- ISDN and CCS7 signalling
- Digital signal processing
- VLSI components
- Speech processing
- Graphics
- Software tools
- Intelligent network technology

3.1 SOME APPLICATION EXAMPLES

3.1.1 TRANSMISSION

Optical fibres, and to a lesser degree, digital microwave provide a cost effective solution for high bandwidth long distance interconnections. Analog and digital radio in VHF and UHF band, on the other hand is excellent for short range requirements in both urban and rural areas. Less expensive multiple access radio systems are expected in the near future.

3.1.2 SWITCHING

The cost of switching has been dropping significantly over the past several years. The new systems provide higher call handling capacity, digital connectivity and, above all, transit capability which simplifies networking in the rural/low density areas. Further savings are possible by improved integration of radio transmission with the switch, eliminating expensive line circuit components. Digital cross connect systems with network management control are very important for

improved utilization of resources. This helps in adapting the network to the traffic needs in a dynamic manner.

3.1.3 ISDN/CCS7

The advantages of the new technology are obvious. However the full potential of CCS7 signalling system remains to be exploited. This provides a powerful messaging capability that goes far beyond handling the signalling function. It can be utilized for network management and control, introduction of novel services and help in setting up virtual private networks. CCS7 will be the key element in all future networks. Adding further networking and processing capability (e.g. transaction processing) it leads to the powerful and versatile intelligent network technology.

3.1.4 NETWORK TOPOLOGY

One has to take a fresh look at the way in which new networks are designed. Traditional methods based on thumb rules may not be valid in the new context. Integration of switching with transmission and the availability of powerful messaging capability permits us to implement networks in which the switches are placed closer to the traffic, thus reducing the cost of switching as well as transmission. Also remote operation and maintenance can be introduced without much difficulty.

3.1.5 POWER REQUIREMENTS

This aspect is important especially in the developing countries and the rural areas where the main power is either very irregular or totally absent. Very low power components based on complementary metal oxide silicon are now available in wider range and higher complexity. This makes it possible to have very low power systems which can be powered optionally by solar cells. An area that seems to have been neglected is the solar cooling (refrigeration). Development of this technology will provide us a reliable low cost cooling solution for desert areas. A number of solutions based on passive and active (absorption) techniques are available but they are yet to be applied in large scale for telecommunication purposes.

3.1.6 UPGRADATION OF OLDER NETWORKS

One of the serious problems in modernization is the upgradation of older networks. The wide gap between the facilities provided by the new systems and the older systems forces us to consider full replacement. However this is not necessary in all the cases. If there is a reasonably reliable and efficient basic POTS network, then the more advanced facilities such as call detail record, subscriber "controlled" long distance calling, automated operation and maintenance, network management and control can be introduced by an intelligent add-on interface. Such an interface can be implemented through a microprocessor based signalling handling unit and a set of computers (data bases) interconnected by a packet network. Such intelligent add-ons can also be used for implementing 800 and 900 types of services, credit card calling, etc.

4. INTELLIGENT NETWORK TECHNOLOGY

As the customer needs become more and more complex and varied, their implementation needs more efficient ways of handling messaging and data base engineering and management. The focus shifts from the traditional transmission, switching and terminals to signalling and networking. Through this is evolving the new intelligent network technology. This is expected to have significant impact on the new networks and facilities.

Networks that are termed "intelligent" are still in the process of evolution. The first stage is the IN/I. In this phase, essentially the "intelligence" is "added on" to the old networks. Existing network expansion based on relatively dumb switches (the service switching point, SSP) interacting with an intelligent centralized data base (the service control point SCP) which also contains several service specific application software and customer records. This permits introduction of new services at the highest level. The inherent limitation of this approach is its service dependent software; each service requires a new software package that in turn requires considerable effort and time. However it does have an advantage in its ability to upgrade old networks for new services.

The next stage of advancement is the IN/2 network. This aims at providing a fully service/application independent architecture to meet a wide range of new, expanding services with an easy method of service creation and management. Implementation of this needs more intelligence at the local switches and several new hardware and software elements at each node. There is a standardized service creation environment which allows new services to be defined and implemented without reference to the specific network elements. The facilities also permit quick and easy way of protyping new services. All this would need significant upgradation of local exchanges which, without network expansion, may not be cost effective.

IN/I+ is an intermediate solution based essentially on existing hardware and software. Here the intelligence is not fully distributed throughout the network but at certain specific points which standard functional messages (service independent) to the local switch.

4.1 THE PRIVATE VIRTUAL NETWORK (PVN)

Among the several facilities that are provided by the intelligent IN, the ability to create private virtual networks (PVN) is very important. PVN will permit implementation a service with which a business can tailor its own network based on the resources of the public network with IN capability. The user pays for the resources and the network guarantees that the resources will be there when needed without actually allocating a physical resource permanently to a specific user. A network management system is also available to the user along with the PVN.

These PVNs allow the user to implement Value Added Networks (VANs) in a very cost effective way. It is not necessary to make any large investments in permanent physical resources. By having a large IN as a backbone, the public network is able to benefit from the economies of scale and the wide bandwidth provided by the optical fibres.

5. IMPLEMENTATION

Networks of countries such as India, China, Brazil, Indonesia, Chile, Peru and Mexico that are presently in a state of rapid expansion can benefit from the new technologies. As a specific example, the Indian network is expected to expand from the present level of about 5 million lines to over 20 million lines in the next 10 years. A recent study indicates that by adopting only a few of the techniques suggested, the cost per line can be expected to come down by as much as 40%. The most important requirements are:

- Establishing a very high capacity [560 Mbps/140 Mbps/34 Mbps] digital backbone network that will meet the immediate and future needs. This will be based mainly on optical fibres and, to a lesser extent, on digital microwave for interconnecting the main, primary and secondary centres.

- All centres to have digital cross-connect systems (1000 to 100,000 ports) for providing better connectivity, alternate routing and fault tolerance. Facilities include digital patch-panel, 30 channel switching capability and network monitoring.

- Cellular Subset and/or 10/30 channel digital rural radio to be used in rural areas.

- Apart from large switches required for metropolitan areas, small switches (50-500 ports) and medium switches (500-5000 ports) are required in very large numbers. Small switches serving rural areas must be capable of operating without airconditioning and with irregular power supply. All switches will have facilities for handling transit traffic, centralized maintenance and operation.

- Rural radio with 10 channel (ITU) standard and 30 channel (CEPT) standard.

- There is considerable scope for novel cost effective solutions such as integration of the rural switch with multiple access radio for rural application.

- An open ended digital connectivity to facilitate introduction of ISDN-type services in the future.

- Evaluation of intelligent network technology immediately for implement- ing private networks, introduction of new services and facilities and improvement in resource utilization. Smaller

countries can cooperatively share a large network through this technology. It is estimated that savings in the range of 20% are possible.

6. CONCLUDING REMARKS

A number of technologies that have direct impact on telecommunication facilities and cost have been perfected and commericalized in the recent past. Apart from basic hardware and software components, concepts from new emerging intelligent networks are likely to have beneficial impact on the investment and cost of providing high grade communication facilities. Based on preliminary studies, the savings could be in the range of 30-50%.

It is to be noted that the intelligent network technology will provide advanced facilities even without the full implementation of ISDN. Only large scale implementation of CCS7 signalling is required.

Globalization of Training in NEC

Hiroshi Shigehara
NEC International Training, Ltd.
Tokyo, Japan

ABSTRACT

To meet the corporate strategy of globalizing every aspects of NEC Group's activities, education and training function is also in the same process. Various types of education and training are important aspects of this strategy. This paper highlights the training for the technical transfer relevant to NEC products and how globalization is to be driven in this particular area. To help you understand that NEC devotes itself to education and training activities, overview is made to cover employee education and customer training prior to the main subject.

1. INTRODUCTION

1.1 CORPORATE PROFILE OF NEC

(Fig.1)

NEC Corporation, founded in 1899, is a leading international supplier of electronics products that comprise primarily telecommunications systems and equipment, computers and industrial electronic systems, and electron devices. All of the Company's activities are focussed on its synergistic business concept of "C&C", the integration of computers and communications.

In Japan, NEC operates through a network of sixty consolidated subsidiaries, sixty-two plants, and more than three hundred sales offices. Overseas, the Company's seventy affiliates and twenty-three liaison offices cover marketing, service, and research and development activities. NEC as a group consists of about two hundred affiliates in forty-four countries.

The number of employees in Japan and abroad is about one hundred twenty thousand on a consolidated basis and about one hundred eighty thousand people worldwide are working for the entire NEC group of companies. Its products are used in one hundred forty-nine countries in the world. The consolidated turnover in the fiscal year ended March 1991 amounted to twenty-six billion U.S. dollars. NEC Corporation is headed by Mr. Kenzo Nakamura, Chairman of the Board and Dr. Tadahiro Sekimoto, President.

(Fig.2)

This figure depicts the history of innovation in the areas of communications, computers and electron devices and how the computer technology and communication technology have merged to build a compound technology that we call "C&C" supported by device technology.

(Fig.3)

Among the total sales of twenty-six billion U.S. dollars, international business occupies the portion of twenty-three percent. This value gives quite a significant impact to the total corporate management.

(Fig.4)

This graph shows sales by product area classified to communication systems and equipment, computer and industrial electronics, electron devices and others. NEC started its business in the telecommunication area, but nowadays the largest sales comes from computer related area which reaches almost half of its total sales.

(Fig.5)

Let's take a look at the international business. You will find that unlike the story of the total sales, the largest portion is still occupied by NEC's traditional area i.e. communication systems and equipment. Here I would like to draw your attention to how NEC is devoted to contribute to the advancement of telecommunication systems in the world.

1.2 EDUCATION AND TRAINING SYSTEM OF NEC

(Fig.6)

Since you are now somewhat informed of NEC's sizable human resources as well as variety of businesses, you will also appreciate that NEC has been making a significant investment and a lot of effort to establish a well-organized system for employee education and customer training.

1.2.1 Employee Education

1.2.1.1 Orientation for New Employees

When school graduates join NEC in Japan, they participate in orientation courses off-the-job, for the initial two months, before their specific job assignment is clarified. Even after their job is defined, they will participate further in new employee courses during the first year. This new employee education is planned and executed by Personnel Relations Division.

1.2.1.2 Professional Knowledge and Skills Development

Many organizations are involved in developing professional knowledge and skills required for employees. Let me introduce a few examples of the institutions specialized in technical education.

Institute of Technology Education

Under the current rapidly changing technological environment, many engineers, having a Bachelor of Science Degree, find themselves short of the knowledge and skills that are necessary to handle their job within a couple of years time, after joining NEC. To give them continuing engineering education, the Institute of Technology Education was set up within NEC Corporation in 1979. Courses corresponding to a Master Course and Doctor Course in Universities are provided to the engineers working for NEC group of companies. The number of graduates from this Institute in the last fiscal year reached two thousand six hundred seventy. The number of graduates skyroketted during the last couple of years caused by increasing demand among engineers and thanks to the remote education system, using satellite to be touched upon later.

NEC Technical College

To cope with the corporate strategy of supplying products designed with C&C technologies, it is essential to nurture technicians having adequate capabilities to operate plants where machinery and manufacturing facilities are constantly being upgraded by new applications in electronics and computers. To meet this objective, NEC founded NEC Technical College in 1986 as the first intra-corporate college in Japan approved by the Ministry of Labor.

This college provides two year initial training for high school graduates who wish to work for the NEC group of companies. The curriculum covers the fundamentals of mechanics, electronics and software through lectures and practical training. Moreover, upgrading training for the already skilled workers in NEC is provided to enhance their knowledge in electronics and computer software.

Computer-aided instruction and remote education by satellite are frequently used. The number of graduates from the initial training course is about one hundred twenty per year. Participants in upgrading courses have exceeded one thousand in the last fiscal year, thanks again to satellite education.

1.2.1.3 Managerial Skills Development

To enhance managerial and administrative skills of staff members, NEC set up an affiliate NEC Institute of Management, Ltd., in 1983. This institute undertakes the educational function of the Corporate Human Resources Group and provides a wide variety of courses for the staff members of NEC group of companies such as:

- Management education differentiated by the managerial level in the hierarchy of the organization, ranging from assistant managers to board members

- Self development courses covering a wide variety of knowledge and skills that are required for fulfilling individual jobs

- International business education for the employee involved in international business including overseas transferees and employees of overseas affiliates or offices. Courses cover managerial, administrative, cross-cultural and language skills training.

- Production systems innovators education to develop strategic industrial engineers and upgrade the ability of employees to plan and implement innovative production strategies to enhance the production capabilities

(Fig.7)

- Courses using two-way audio-visual remote education systems via satellite named NESPAC which has been used in NEC's intra-corporate education since 1987. Currently NEC has facilities having this capacity at eleven locations.

(Fig.8)

Marketing and production courses are provided under the course name of Satellite Business College. Courses using low cost one-way visual two-way audio satellite remote education systems named NESPAC-TV that are installed at more than one hundred fifty offices or plants as of the end of October, 1991. This has tremendously expanded the number of participants and thereby contributed to reducing the cost of education. NESPAC and NESPAC-TV are now used as an educational infra-structure by many course providers in NEC as previously exemplified in the section covering the Institute of Technology Education and NEC Technical College.

The number of participants in the courses provided by this institute reached more than twenty-four thousand employees in the last fiscal year. Educational opportunities made available by NESPAC and NESPAC-TV are estimated to be over half million student-days.

1.2.2 Customer Training

1.2.2.1 Domestic Customers

Training for domestic end-users who purchase large systems directly from NEC is mainly made by NEC's product groups. Training for customers on the equipment supplied through distributors or dealers is made by them with adequate and timely support from NEC. In this way, it is very important for NEC to train the trainers of distributors or dealers. This training is provided by the Dealer Support Division of the domestic sales group with the assistance of the product group.

1.2.2.2 Overseas Customers

NEC's overseas affiliates undertake the training for the equipment or systems supplied by them to their customers. NEC's distributors or dealers undertake the training for the equipment supplied by them to their customers with the assistance of NEC's overseas affiliates whenever necessary. In these cases where end-users purchase products directly from NEC Corporation in Japan, training for such customers is made by one of the NEC's wholly-owned subsidiaries named NEC International Training, Ltd. When NEC's overseas affiliates, distributors or dealers need to be trained to provide training for their customers, NEC International Training, Ltd., also undertakes such training. In the following part, I wish to refer to the main subject of my presentation today and focus on NEC's approach to overseas customer training.

2. TRAINING FOR OVERSEAS CUSTOMERS

2.1 ORGANIZATION

2.1.1 NEC International Training, Ltd.

(Fig.9)

NEC International Training, Ltd., or NECITR in abbreviated form, was established in July, 1990, as one of the subsidiary companies of NEC Corporation. By consolidating all of the resources for training, available within NEC group, this unique company was organized to provide a higher level of efficient training to NEC's overseas customers, dealers and employees of overseas subsidiary companies.
Since its establishment, NECITR has been trying to plan and implement the training courses both in Japan and overseas, in order to transfer the knowledge and understanding of the technology of NEC products. We are quite confident that such technology transfer will help those one hundred forty-nine countries to which NEC has supplied its products to progress economically towards the twenty first century.
Our Head Office is located in Tokyo.
(Picture)
As for training facilities, we have three training centers and one hotel-type accommodation.
The first training center is located at the same building as our Head Office in Tokyo.
It has more than ten classrooms of various size, two equipment rooms, one CBT room for the training of central office switching equipment and computer software.
The second center is called Tamagawa Training Center and located in Kawasaki city. (Picture) It has seven classrooms and three equipment rooms for the training of transmission equipment such as Fiber Optics Transmission Equipment and Multiplexer.
The third one is called Yokohama Training Center and located in Yokohama city. (Picture) It has five classrooms and three equipment rooms for the training of Radio equipment such as Microwave, Satellite communication equipment, and Cellular Mobile Telephone system.

As an accommodation for trainees from overseas, we have hotel-type accommodation called Takilio House. (Picture) It has ninety-eight single rooms, two twin bedrooms, one Japanese style room, lobby, lounge, dining room, two kitchens for one's own cooking, KARAOKE room, etc.

The number of employee of NECITR is about one hundred thirty.
Major services we provide, are the planning and implementation of technical training both in Japan and overseas, organizing various seminars both in Japan and overseas, and management and operation of the accommodation for the trainees.

Now, I will explain about major training activities of NECITR.

2.1.2 Training in Japan

(Fig.10)

This shows the number of trainees who came to Japan in the last twenty-five years. As you see here, the number has been increasing steadily. In 1991, we are receiving an average of one hundred fifty trainees every month from various countries of the world.

(Fig.11)

This shows the percentage of the trainees by subject for the fiscal year 1990. Trainees for Microwave and Satellites form the biggest portion followed by Switching, Transmission and Information Processing.

(Fig.12)

This shows the percentage of the trainees by region. Trainees from Asia form sixty-one percent of the total, and followed by Middle East, Europe, Africa and North America.

2.1.3 On-Site Training

(Fig.13)

The number of trainees who were trained by our instructors at the customer's premises for the last six years is shown here.

(Fig.14)

The percentage of the trainees by subject for the fiscal year 1990 are indicated here. Trainees for Switching form twenty-four percent, followed by Microwave & Satellite, Transmission and Information Processing.

(Fig.15)

The percentage of the trainees by region highlights the fact that trainees from Asia form the biggest portion and form almost half of the total. Then, Latin America thirty-nine percent, followed by North America and Europe.

2.1.4 Organizing Seminars

NECITR organizes various seminars both in Japan and overseas. In Japan, we organize at least two two-week seminars every year. The theme of the current seminar is "Network Planning".
In addition to this, we send several experts to overseas locations to organize seminars on C&C Technology. For these we invite officers, engineers, professors, students from the government, carriers, universities, and others of the specific country.

2.1.5 Other Activities

(Fig.16)

This shows other activities of NECITR for trainees.

We provide the product training course to the sales engineers of NEC's overseas subsidiary companies. Also, we provide the training course to our own instructors so that they continue to strengthen their teaching skills. We provide trainees with Japanese language course or basic technology course as an option. They can take these courses in the evening after they finish the technical training course if they wish.
Further, we arrange factory tours or study tours for trainees so that they can get more knowledge about NEC and Japan. (Picture)
As a special gesture to the trainees, we offer them an opportunity to visit Japanese family to experience a typical Japanese style of life. (Picture)

2.2 GLOBALIZATION OF TRAINING

As one of the multi-national companies, NEC's operations are worldwide.

(Fig.17)

As shown here, NEC has twenty-six manufacturing affiliates in fifteen countries, forty-four marketing & service affiliates in twenty-three countries, and twenty-three liaison offices in twenty-one countries. In total, ninety-three operations in forty-three countries.
This means that NEC has been globalizing its operations not only in manufacturing but also in marketing, engineering and service. Of equal importance has been the expansion in Research and Development. Now, I would like to explain how NEC is globalizing in the field of training.

2.2.1 Instructor

NECITR has forty-five full-time instructors within its organization. Among them, we have twelve non-Japanese instructors and their nationalities vary as follows:

Guatemala	1
Mexico	2
Philippines	1
Singapore	2
Sri Lanka	4
U.S.A.	2

They are experts in each field of technology and can instruct either in English or Spanish or Chinese.

2.2.2 Global Sharing System for Instructors

As already shown, NEC has many subsidiary companies overseas. Most of them have their own training department and training facilities for their customers or dealers. The instructors of these companies have enough expertise to teach their customers or dealers. NEC provides the necessary technical-transfer to these instructors. From time to time, we organize a special course to retrain these instructors in Japan.
Therefore, these instructors maintain the same level of expertise in each of their technical field as Japanese instructors.

(Fig.18)

On the other hand, as shown here the training demand varies up and down based upon the month of the year. We have two peak times, that is, spring and autumn, and two low times, that is, summer and winter. The gap between the peak time and low time is quite large. Because of this, it is very difficult to adjust the schedule of the instructors.
If we maintain the number of instructors based upon the peak time, then we will not be able to fully utilize their talents during the low periods.
On the contrary, if we maintain the number based upon the lower periods, we may face a severe shortage of instructor at the peak time. With this in mind, it is more efficient and economical to share the instructors on global basis. The peak training time of each country is different country by country.

(Fig.19)

This identifies the key aspects of the actual operation of our Global Sharing System for Instructors.
As you see here, we are sharing the instructors among NECITR and other NEC's overseas companies. For example, we ask an instructor in New Zealand to go to Iran to offer instruction to one of the customers in Iran. Or we ask an instructor in Malaysia to come to Tokyo to instruct a group of trainees from overseas.
This system helps us to cope with the up and down of training demand in each country. It also gives the instructors a broader opportunity and incentive to go to a foreign country and gain additional experience.
Moreover, from the viewpoint of the limited human resources, this system is the most efficient way of utilizing our human resources on the global basis.

Next, I would like to introduce another example of globalization in the area of training. In the U.S.A., one of the subsidiary companies of NEC participates in the overseas telecommunication projects together with the U.S.A. firms. In accordance with the contracts, NEC's subsidiary company can send the instructors to overseas customers, such as Philippines, Mexico, Korea and Canada. Or NEC's subsidiary company can also receive the trainees from overseas at their training centers.

2.2.3 Global Sharing for Course Material Development

In addition to the Global Sharing System for Instructors, we share the development works for course materials, such as training text, CBT modules, etc., among NEC's overseas subsidiary companies. This also helps to utilize the limited human resources to the fullest extent.

3. CONCLUSION

This paper covers briefly the global activities of NEC in the field of customer training. NEC views the customer training as an extremely important corporate activity-no less than R&D, manufacturing or marketing. NEC designs and manufactures its products to the highest standards of quality and reliability.
However, it is the customer's operation and maintenance staff that really puts our products to the test. It is in those areas of placing the equipment into service and being able to operate and maintain it over many years that the important elements of training are most important.
Therefore, we try to always stand behind the products and customers by providing the best training using the latest technology of teaching as well as the best quality of course materials. This, after all, is the meaning of our corporate philosophy: "NEC strives through C&C to help advance societies worldwide toward deepened mutual understanding and the fulfillment of human potential."

THE HARMONIZING OF PATENT AND COPYRIGHT LAWS OF PACIFIC RIM COUNTRIES

Stephen E. Baldwin and Daniel L. Appelman
Heller, Ehrman, White & McAuliffe, Palo Alto, California

Henry K. Woodward
Townsend & Townsend, Palo Alto, California

ABSTRACT

The intellectual property laws of Pacific Rim Countries are reviewed. This review includes an analysis of the patent and copyright laws of Pacific Rim countries, notes differences in the various laws, and discusses efforts underway to harmonize the laws by the World Intellectual Property Organization (WIPO), headquartered in Geneva, and in the General Agreement on Trade and Tariffs (GATT) treaty negotiations. The laws on patents will be reviewed first, then the laws on copyrights, and the rapidly developing area of patentable software will be reviewed.

Intellectual property including patents on inventions and copyrights on writings, audio-visual material and other works of art, are capital assets and strategic tools in business planning. These types of intellectual properties can be of significant importance and value in the tele-communications field. However, differences exist in the intellectual property laws of Pacific Rim countries in recognizing and protecting intellectual property which impact trade between countries and investments in countries.

India, the People's Republic of China, and Thailand were reported in the BNA Patent, Trademark and Copyright Journal, Vol. 42, May 2, 1991, by the Office of the U.S. Trade Representative, to be among the worst offenders of intellectual property rights protection for, and market access to, U.S. citizens relying on intellectual property. Piracy of all forms of intellectual property was reported as widespread in China, which has offered neither product patent protection for pharmaceuticals and other chemicals nor copyright protection for U.S. works. However, new regulations for the protection of computer software in China became effective October 1, 1991. India has short terms of protection, broad compulsory licensing, and lack of protection for certain classes of inventions. Thailand was cited for failure to enforce copyrights and deficient patent protection.

This paper reviews the patent and copyright laws of Pacific Rim countries, notes differences in the various laws, and discusses efforts underway to harmonize the laws by the World Intellectual Property Organization (WIPO), headquartered in Geneva, and in the General Agreement on Trade and Tariffs (GATT) treaty negotiations. The laws on patents will be reviewed first, then the laws on copyrights, and the rapidly developing area of computer software protection will be reviewed.

PATENTS

Key issues in harmonizing the laws on patents are the definition of patentable subject matter and exclusions, the publication of pending applications, the terms of patents, and enforcement of patent rights including compulsory licensing. Other key issues include entitlement to patents by either the first inventor or by the first applicant to file a patent application, the requirement for absolute novelty when the application is filed versus grace periods based on pre-filing activities of the applicant and others such as publication, commercial use, and sale of the invention.

The U.S. and the Philippines are the last two countries to grant patents based on first-to-invent rather than the first-to-file a patent application. However, the section on Patent, Trademark, and Copyright Law of the American Bar Association has recently adopted a resolution favoring in principle adaption of the first-to-file rule in the U.S. if the adaption were part of a patent harmonization treaty, wherein other countries agree to changes in their patent system sufficiently beneficial to U.S. applicants and their assignees.

In Asia, Japan has one of the most developed intellectual property laws, and some countries in Asia have patterned their laws after the laws of Japan. While Singapore, Malaysia and Hong Kong as a crown colony are still influenced by the British legal system, the laws of the various countries remain diverse.

The definition of patentable subject matter typically requires novelty (absolute or with grace periods), industrial utility (as opposed to theoretical or scientific principles or mathematical algorithms), and non-obviousness (inventive merit) and supported by an adequate written specification. Exclusions can include inventions contrary to public order, health or morals, medical procedures on humans, pharmaceuticals, and certain chemical compositions including substances manufactured by the transformation of the atomic nucleus. The patentability of computer software remains an issue in most countries, as discussed later. Terms of patents can be measured from application filing dates or from patent issue dates. Compulsory licensing can be required for certain patented inventions

particularly in the medical field or if the patented invention is not being "worked" in the country granting the patent.

Most countries belong to the Paris Convention which accords the original application filing date to patent applications in other countries which are filed within one year of the first filing date. Notable exceptions include Taiwan, the Andean Group of South America, India, Thailand and Singapore.

In the ongoing WIPO negotiations the U.S. is being asked to make a number of changes to its patent laws besides the first to file right of priority. These changes include eliminating grace periods for publications and public uses of third parties, according to foreign applicants a one-year grace period for their own public use and publications from their first foreign filing date; making prior public use, sale or disclosure in foreign countries part of the prior art; eliminating secret commercial use by an inventor or non-public sale before the grace period as a basis for invalidating patents; and eliminating the experimental use exception to prior commercial use. Additionally, pending patent applications would be published two years after their filing date; and the term of U.S. patents would be set at 20-25 years from the filing date of the earliest U.S. application on which priority is based.

These provisions are included in a Basic Proposal Draft Treaty, negotiated by a Committee of Experts which has been meeting since July 1985 at WIPO in Geneva. The GATT negotiations in the Uruguay round of talks includes a Trade-Related Aspects of Intellectual Property rights, or TRIPS, negotiating group which has formulated an agreement with many of the basic provisions of the WIPO draft treaty included therein. This agreement was to be presented to the U.S. Congress as part of a larger trade agreement, but disagreements among the parties as to agriculture trade issues have stalled the GATT negotiations.

While the harmonizing of patent laws along the lines of the draft WIPO treaty will most likely occur, enactment of the treaty will probably depend on, and be part of, broader trade agreements. In the meantime, the U.S. is encouraging Pacific rim countries to review and strengthen their patent laws as necessary to accord protection for the patent rights of U.S. citizens doing business with and in the countries.

COPYRIGHTS

The Berne Convention has become the principal vehicle for the standardization of copyright protection worldwide. However, the following countries of the western Pacific region are not signatories to it: Burma, Laos, China, North and South Korea, Vietnam, Kampuchea (Cambodia), New Guinea, Indonesia, Taiwan, Thailand and Singapore.

The United States and several other industrialized countries have taken the lead in trying to convince these countries to reform their copyright laws. Their principal motivation and poli[illegible], of course, has been to ensure that owners of exported copyrighted works are adequately protected against domestic infringers in those countries. These industrial countries have been particularly active in multilateral and bilateral negotiations, in participating in the Uruguay Round of the GATT and in the WIPO. The United States, at least, has also sometimes threatened to impose trade sanctions against countries who refuse or are slow to amend their copyright laws to conform with "international trends".

The activities of the United States and the other proponents of strong international copyright protection are subject to countervailing policies adopted by many of the less developed countries. These countries view any restrictions on copying and any requirement of substantial compensation to foreign manufacturers and authors as being inconsistent with their own agenda for rapid economic and social development.

The United States has recently been a strong advocate for the inclusion of "western" standards for intellectual property protection in the GATT. In that forum, it has sought agreement among GATT signatory countries, including many of those listed above, to grant all of the "economic" rights guaranteed by the Berne Convention plus some additional obligations. As of this writing, the Uruguay Round of the GATT has resumed with copyright protection on its agenda.

Over the last two years, the WIPO has attempted to develop a consensus in favor of the adoption of a Model Copyright Law based upon the obligations of the Berne Convention. That consensus has not yet emerged; and WIPO's efforts have further revealed the underlying policy disputes between the needs of the industrialized and the developing countries. Nevertheless, most observers predict some sort of Model Copyright Law to emerge from WIPO within the next few years.

Japan is a member of WIPO and a signatory to the Berne and Universal Copyright Conventions. However, in the opinion of many, copyright protection in Japan for certain classes of works of authorship is seriously deficient. One of the most significant problems has been the double standard in the protection of sound recordings. The law had granted domestic manufacturers and performers considerable protection but had not extended the same rights to authors and owners of foreign works. As a result, pirating of foreign recordings and lack of compensation from rental shops was common.

Major revisions to Japan's copyright laws concerning the protection of sound recordings went into effect on January 1, 1992. Under the

recent amendments, foreign manufacturers and musical performers are now granted exclusive rights to their recordings for one year, after which they would be entitled to specified royalties for use of those recordings, including rental. These amendments give domestic and foreign recordings the same level of protection and therefore remove the double standard noted above. However, many in the recording industry feel that the short term of protection and extremely low compensation from rental shops leaves both groups of manufacturers and artists substantially undercompensated.

Until recently, South Korea had virtually no copyright protection either for foreign or domestic authors. In 1990, the International Intellectual Property Association requested that the United States Trade Representative identify and investigate South Korea because of its inadequate enforcement of copyright laws.

As a result of this and other pressure, the government has enacted significant reforms. South Korea now has a copyright registration system and other services and procedures which make protection more feasible. South Korea is a signatory of the Universal Copyright Convention but not to the Berne Convention. It is not a member of WIPO.

Despite some progress in reforming its copyright regime, South Korea remains a major problem area to foreign exporters because of its failure to enforce its new laws. Fines for infringement are still minimal and jail sentences are rarely imposed, even for repeat offenders. Counterfeiting and piracy of videos, textbooks and computer software are still the norm rather than the exception.

Thailand has long been among the worst countries of the region with respect to providing copyright protection to foreign authors. Particularly notable are its onerous compulsory licensing laws. The government can require foreign firms selling copyrighted works in Thailand to license those works to Thai firms for nominal fees.

In 1987, the Thai government submitted new copyright laws to its Parliament which would have improved the situation dramatically. However, the legislation caused a no-confidence vote and Parliament dissolved. Ever since, Thailand has refused to amend its copyright laws despite particularly intense pressure from the United States.

Like Thailand, the Philippines affords very little protection for copyrightable works. There is no protection for sound recordings, for example, and very little in the way of enforcement for any works of authorship. Like South Korea, the government of the Philippines has instituted a compulsory license system for certain classes of works, including textbooks and reference books. Its copyright laws also contain formalities which are incompatible with the Berne and Universal Copyright Conventions.

Several years ago, Hong Kong amended its copyright law to bring it into closer conformance with emerging international standards. However, recent proposed changes have caused some to question Hong Kong's commitment to vigorous copyright protection. Those proposals include decriminali-zation of copyright infringement and the termination of search and seizure raids upon allegedly infringing manufacturers. The outcome of these proposals bears watching.

Of all the countries in the western Pacific region, the People's Republic of China has perhaps made the most progress in recent years in instituting copyright protection which is compatible with international trends. Its first copyright law became effective last June, and it purports to protect the moral and economic rights of Chinese and foreign authors alike.

However, much work remains for the PRC. The new law only protects foreign works first published in China and other foreign works to the extent protected by international treaties to which the People's Republic has acceded. Since it hasn't acceded to any international treaties yet, the practical effect is that foreign works first published elsewhere are virtually unprotected. The new law also provides for compensation for damages "according to circumstances". This is, of course, a very subjective standard which makes for considerable uncertainty and a lack of predictability in the area of enforcement. The law provides that anyone can use published works without permission of the author except when the author issues a statement prohibiting use of the works. Finally, China has promised to issue regulations which would assist in implementing the new law. To date, no such regulations have been issued. Thus it remains to be seen to what extent China's new copyright law will actually improve copyright protection for both foreign and domestic authors.

We expect the developing countries to continue to resist enhancements of the rights of foreign copyright owners, although the pace of change has increased in the last few years. As the foregoing survey shows, however, much remains to be done to harmonize the copyright laws of the western Pacific region countries with the Berne Convention and other international standards adopted by the more industrialized countries.

PATENTABLE SOFTWARE

The United States Patent and Trademark Office (USPTO) has published guidelines regarding the questions of patentable subject matter that relate to computer programs and, more particularly, to mathematical algorithms.

A mathematical algorithm has been defined under U.S. case law as a procedure for solving a given type of mathematical problem. A mathematical algorithm is, per se, not patentable subject matter; however, a patent application drawn to subject matter otherwise patentable does not become unpatentable simply because it uses a mathematical formula, computer program, or a digital computer. The USPTO has adopted a two part test for mathematical algorithm, and whether it satisfies as statutory subject matter (i.e., whether a claim of invention preempts non-statutory subject matter as a whole requires a two step analysis).

First, it must be determined whether the claim directly or indirectly recites a mathematical algorithm, for a claim which fails to even recite an algorithm clearly cannot wholly preempt the algorithm itself.

Secondly, if the claim does recite in part a mathematical algorithm, the claim must be further analyzed to ascertain whether in its entirety it wholly preempts that algorithm.

The USPTO has been wrestling with this particular area in connection with patentable subject matter, particularly in view of the large number of patent applications filed with utilize some form of a computer program or computer process.

In a recent case (1989), the United States Court of Appeals for the Federal Circuit upheld the patentability of subject matter that included a mathematical algorithm. In that case, an approximation to a conventional equation for autocorrelation coefficients had been developed for use in pattern recognition. The applicant in that case had claimed a Read Only Memory (ROM) as part of the apparatus. The Court of Appeals for the Federal Circuit was satisfied that that the claim of patentable subject matter was for a specific piece of apparatus, and therefore that the second part of the two part test was not met. As a result, the subject matter was found to be patentable.

The USPTO is evaluating such applications on a case by case basis, and is looking carefully toward whether the first part of the test is met (whether the claim directly or indirectly recites an algorithm); and secondly, whether the claim in is entirety wholly preempts the mathematical algorithm.

It is the USPTO position that mere recitation of structure (such as a ROM) within the claim does not necessarily mean the claim passes muster. However, once it is determined that the claim is truly drawn to a specific apparatus, it necessarily follows that the apparatus is statutory subject matter. True apparatus does not invoke the mathematical algorithm exception, because the mathematical algorithm remains free for use by anyone not employing the specific apparatus, i.e., there is no preemption in whole or in part of the mathematical algorithm itself.

However, if the applicant in a particular case includes the recitation of a "means" for performing a specific function, the USPTO position is to look very carefully at such recitations. Such types of claims are given their broadest reasonable interpretations and then it is the applicant's burden to show that the functionally defined disclosed means do not encompass any and every means for performing the recited functions, because otherwise such an interpretation would then preempt the mathematical algorithm itself.

Hence, the applicant has the burden of satisfying the USPTO of the adequacy of the claim language with respect to mathematical algorithms.

Other Patent Offices have adopted the same or similar views in connection with computer software.

For instance, the Australian Patent Office has adopted the same test as developed by the U.S. Courts; however, this is not to say that inconsistencies of application do not occur in particular cases in Australia. However, the general approach of Australian practice in this area is similar to that of the U.S. practice.

In the People's Republic of China, the Chinese Patent Office is currently taking the position that, in the case where a patent application is involved only in computer programs or mathematical algorithms, no patent protection will be granted for these programs or algorithms. However, in the case where a patent application is involved in a system, device or apparatus that comprises an interacted combination of a plurality of pieces of software and hardware, then that system, device or apparatus may be granted protection for its technical solutions as a complete self-contained entity.

The Japanese Patent Office also does not provide patent protection for a mathematical algorithm, per se. The patentability of an invention in Japan related to a computer program or mathematical algorithm is first subjected to a test to determine whether or not the software is combined with specific hardware for application to a specific field of industry. Examples of such cases are electronic calculators, IC cards, wordprocessors, and electronic game equipment. In such examples, software stored in a ROM provides a specific function in combination with the hardware. This type of invention could be patentable in Japan (presuming the other requirements for patentability are satisfied).

In areas in Japan where the software is not tied to a specific piece of apparatus, a further test is carried out to determine whether or not the software utilizes a specific property or structure of hardware resources provided for a computer system. If the result of the test is affirmative, a further test is made to determine whether or not the software can be recognized as a method for controlling or effectively utilizing the specific property or structure of the hardware resources, or whether the function provided by the software can be grasped as providing a device as being combined with the hardware resources. This is illustrated in cases such as operating systems, file access controls, file control systems, and the like.

In the Republic of China (Taiwan), mathematical methods are treated similar to scientific principles, much as in the United States,and are not considered patentable.

The test in Taiwan appears to be similar to that of the U.S. in terms of whether a computer is substantially used and, if so, whether the computer is substantially an apparatus.

The position of the South Korean Patent Office is apparently that computer software itself cannot be protected by a patent in South Korea. A process patent may be claimed in a case where computer software is used for the operation of machines. As is the case in the United States, a mathematical algorithm, as such, cannot be the object of a patent because a mathematical algorithm does not use a natural law, but is considered to be a representation of the natural law itself. A process patent in South Korea may be claimed only in the event that a natural law has been used in the computer software for the purpose of solving a specific problem.

INFORMATION TECHNOLOGY-LED DEVELOPMENT: CAN THE LESSONS BE TRANSFERRED?

A. Lee Gilbert
Regional Advisor for Technology Transfer and Development
United Nations ESCAP, Bangkok, Thailand

Ruchadaporn Lertphokanont, Policy and Plans Analyst
National Economic and Social Development Board
Royal Government of Thailand, Bangkok, Thailand

1. ABSTRACT

Although advocates of technology-led development claim that information technology (I.T.) is a leading sector for national development, the policies required to obtain this potential are unclear. This policy research paper contrasts a decade of efforts by the governments of Singapore and Thailand to use I.T. to support their economic and social development, indicates why I.T. policy which is successful in one context may not transfer to another, and recommends an agenda for national I.T. planning.

2.0 INTRODUCTION

Information technology (I.T.) is not new to Asia [1]. However, recent trends in technology development, in the use of information in the economy, and in the interaction between the public and private sectors raise the value of I.T. as a development tool. The issues generated by these trends are similar in developed and less-developed economies.

2.1 I.T. AND DEVELOPMENT

From the functional perspective, I.T. includes material objects and related techniques used to capture, store, retrieve, process, transform, transmit, or display machine-readable information. From a user view, I.T. is the "package" of hardware, software, and techniques required over the life of an application [2]. This package also includes the arrangements necessary for use, and thus implies skilled technical workers, knowledgeable managers, and competent users. Policy affects these resource factors, and influences organizational motives to adopt new technology.

Increasingly, sound I.T. policy can make a strategic contribution to national development, because: (1) Capability and performance are increasing, while costs have declined, (2) Individuals and organizations are rapidly learning to use this new technology, and perhaps more importantly, (3) data processing and telecommunications technologies are converging, so that I.T. can now be used to facilitate interorganizational and international cooperation, with dramatic consequences for national development.

2.2 FALLING COSTS, RISING CAPABILITIES

Long ago, radio and television signals crossed national borders. Motorola's recently announced plan for a global mobile cellular system linked via 77 "Iridium" satellites will enable users to make and receive calls from anywhere in the world [3]. Today's technology-led revolution, based on freedom from national cable-and-wire networks, will reshape international trade links.

Hardware costs have fallen more than twenty percent each year over two decades. Improved software-based capabilities to manage information and in data transmission speed and computing power are equally important. Computer-aided vision can now improve product quality, and other tasks which were once technically impossible or uneconomic can be automated. Combined, these trends in technology open more possibilities for I.T. use than can be implemented, and discretion must be exercised to align new uses with long-term objectives.

2.3 RISING EXPECTATIONS, LAGGING SKILLS

Such successful uses of information technology are widely publicized, and expectations have risen. However, successful use of any new technology requires both technical and management skills, plus a supportive organizational and social environment. This means that planning for the public sector use of information technology must be carefully integrated with manpower development planning and public education.

2.4 CONVERGING TECHNOLOGIES

When computers and telecommunications were based on divergent technologies, data transfers between computers were difficult and expensive. As digital designs replaced analog circuitry, the technological basis for computer and telecommunications hardware converged, thus facilitating interaction between computers at different sites. This trend means that policy and planning for the use of these two information technologies must now be integrated.

3.0 I.T. AND NATIONAL COMPETITIVENESS

Harvard Business School Professor Michael Porter's model of national competitive advantage [4] portrays industrial restructuring as a process of reconfiguring the joint efforts of multiple enterprises in selected industries to make them internationally competitive. According to Porter, economic linkages, geographic location, and market structure are key factors within an industry. External to an industry, the focus is on the effect of public policy on the business climate, public investment, trade facilitation, and the climate in which technology is developed, transferred, and used. Only product innovation and reconfigured value systems for key enterprises in specific industries (and not low wages or raw materials) provides sustainable national competitive advantage.

Public and private sector organizations create value through a combination of physical and information activities. Banks and many Ministries deal mostly with information. Cement manufacturers and public works crews mostly carry out physical activity, but also generate and use information. Some organizations are highly dependent on information flows: neither international airlines nor modern hospitals could function without computers and telecommunications.

If information adds value to activity (e.g., airline ticket data is used for scheduling, pricing, and billing), rapid information flows may improve financial performance. The Singapore Tradenet case[5] illustrates how information technology affects business velocity.

International trade revolves around information: about the goods, the parties at interest, the modes of transport, the dates of departure and arrival, and the payment of various fees and the exchanges between the parties. To defend its role as a leader in port services, Singapore first automated operational processes in trade-related public agencies. "We were able to turn Customs and Excise into an agency that speeds up trade, not slows it down," according to the agency Director-General, Lee Yew Kim. The strategic payoff came only later, when the government built the Tradenet value added network to provide on-line links to the entire trading community, including Customs and Excise, the Trade Development Board, sea and air ports, shippers, receivers, air cargo operators, freight forwarders, banks, and insurance agencies, across international boundaries. Within two hours of notification by an arriving ship, freight forwarders using Tradenet can obtain import permits, clear customs, pay duties for cargo going ashore, and obtain export permits for outbound cargo. This case demonstrates that (1) telecommunications and computer technologies can be sources of national competitive advantage, and (2) the public sector role in planning and implementation is critical.

This paper compares the I.T. policies of two dissimilar South East Asian nations. Singapore is an entirely urban island nation located near the equator at the southern extent of the South China Sea, with a population of 3 million occupying just over 600 square kilometres. After its 1959 independence, Singapore's infrastructure investments and policies encouraged growth in distribution, trading, and banking services, and in light industries such as electronics. Its success in the 1970's was accompanied by high employment and rapidly rising wages. Social development policies were primarily directed toward functional goals such as housing and health care. By 1990, per capita domestic income exceeded U.S. $10,000, and health, literacy, and other development measures exceeded many industrialized nations [6].

Bordered by Malaysia to the south, Burma to the west, Laos to the northeast and Kampuchea to the east, Thailand's 514,000 square kilometres shelter a population of 57 million people. Agriculture is the mainstay of the Thai economy, and its industries were originally linked to agriculture. Import substitution policies gave way to an export orientation in the early 1960's. Growth was slow until the 1980's, when foreign investment and construction multiplied, and the economy grew at a sustained rate of nearly 10 per cent. Today, a structural shift from agriculture towards industry, and from increasing production volume towards improving efficiency and quality, are seen as prerequisites for competitiveness in the rapidly changing world economy. The current per capita domestic income is about US $ 1400 [7].

4.0 SINGAPORE

In 1980, Singapore policymakers envisioned a post-industrial society in which high technology and new skills would displace labor intensive industries, and information would become

a primary economic good. In the interim, automation and widespread use of information technology in the private and public sectors, supported by the introduction of technological culture to the community, would raise productivity. Central control of short and long-term incentives (balanced with powerful disincentives) allowed policymakers to influence supply and demand and to regulate entry in key markets [8].

Using this power, it took Singapore only one decade to put a national information technology infrastructure in place, to develop systems to support essential government activities, and to accelerate the use of information technology by private and public organizations outside the government's direct control.

4.1 SINGAPORE, I.T., AND DEVELOPMENT

By 1980, simple factor endowments (raw materials and unskilled labor) were declining in strategic value over time, while international competitiveness demanded more advanced factors (specific skills, scientific infrastructure, and access to high-technology services and supplies). Singapore policymakers expected public sector computerization to increase productivity, to provide a visible example to the private sector, and by upgrading the infrastructure and labor force, to attract investment from higher-level industries. Thus, computer and telecommunications infrastructure became a formal element in the national development strategy [9].

Formed in March 1980, the Committee on National Computerization (CNC) shifted the economic role of information technologies in the private sector and in the government. By 1980, hardware was the least expensive element of the labor-intensive systems development process, and manpower was the limiting factor. The strategic transformation from a labor-intensive to a value-added economy demanded improved public sector information management, and Singapore's emerging role as Southeast Asia's telecommunications hub required software development and maintenance services. Those sectors received priority [10]. The CNC under the Minister of Trade and Industry, focused on developing the human resources and infrastructure necessary to build a core of information systems for the government. The CNC formed the National Computer Board, a special-purpose agency outside most Civil Service controls, to carry out this task. NCB formed a wholly owned software house and a commercial training firm, and at one point employed one-fourth of the national pool of skilled manpower in support of the Civil Service Computerisation Programme (CSCP) in key ministries [11]. The realization that the supply of technology must be coordinated with demand was attributed to a private sector marketing executive on the CNC panel. This simple principle permeates the Singapore I.T. strategy.

4.2 TECHNOLOGY TRANSFER DEMAND FACTORS

Powerful incentives increased the demand for information technology products and skills [7]. The Economic Development Board (EDB) policies shifted resources from labor-intensive to skills-based firms. US $ 50 million per year in employer payroll taxes was devoted to grants and subsidies for training and development programs. Low-interest EDB loans helped local firms buy hardware. The EDB also subsidized I.T.-related consultants. Tax policy was changed in 1983 to allow full first year write-off of most computer-related equipment, and no import duties were levied. These measures reduced the organizational cost and risk of adopting I.T..

The Civil Service and government-owned enterprises brought the first computers to Singapore in the late 60's and early 70's. The Ministry of Defence acquired minicomputers, while a mainframe and systems group in the Ministry of Finance served several agencies. However, the public sector was slow to adopt telecommunications or new technologies such as word processing. The Ministry of Finance tightly controlled most public sector computer acquisition and services during this era. During the later CNC era, new I.T. was more welcome. Microcomputer use exploded. Word processors were widely used. The public sector became a major user of I.T. products and services. By mid-1985, the CSCP ministries operated 16 mainframes and superminicomputers, with a total on-line data storage capacity of ninety gigabytes (million million) characters [12].

4.3 TECHNOLOGY TRANSFER SUPPLY FACTORS

The EDB actively courted overseas sources of information technology, while NCB encouraged small software houses to compete with large computer companies. Many experienced computer professionals working in Singapore were expatriates in temporary roles, working for vendors in product support roles or on contract to clients. The 500 computer installations of all types in Singapore were staffed

by only 850 I.T. professionals in 1980. The few public sector analysts and programmers were supporting obsolete batch systems. From this narrow base, the Singapore manpower pool increased to more than five thousand computer professionals by 1986 [13].

The nation's compact size facilitated the development of its communications infrastructure, and the state-owned Telecoms Authority (TAS) led South East Asia in voice and data communications technology. Most data communications flowed over leased lines until modem licensing was liberalized in 1983. By 1985, TAS provided direct links with more than 200 international destinations through its extensive undersea cable and satellite network. TAS offered packet-switched communications, facsimile transceivers, electronic mail, telex, and database (Datel) services, and its cellular mobile telephone and radio paging services grew rapidly [14].

4.5 EVALUATING NATIONAL POLICY

The CNC strategy leveraged Singapore's foreign trade links to acquire skills and technology which would not otherwise have been attracted to Singapore's small market. Outward transfers of locally developed technology (either within the region or to industrialized markets) was a low priority. A six-fold increase in the number of working I.T. professionals over a six-year period was remarkable because they were fully absorbed by the local market [15]. This reflects the success of CNC policy to reduce risks, costs, and other obstacles to change.

5.0 THAILAND:

Six five-year national economic and social development plans have guided development in Thailand from 1961 to 1991. Awareness of the role of science in national development is a fairly recent trend, first expressed in the Fifth Plan. Information technology is seen as a tool to improve communications and accelerate national development. Over the past five-years, the Ministry of Science, Technology and Energy has greatly strengthened the national science and technology infrastructure, while the Ministry of Transport and Communications worked to build a modern communications infrastructure as a platform for industrial development.

5.1 DEVELOPMENT STRATEGY

The industrial element of Thailand's economic and social development plan is based on the "lead industries" concept. The Ministry of Science, Technology and Energy (MOSTE) identified the electronics and information technology sector for promotion and expansion. MOSTE plans to strengthen national technological capability and to coordinate technology policy by [16],

1. Expanding science and technology cooperation agreements with technologically advanced nations.

2. Improving production efficiency and quality.

3. Forming a Committee which will promote information technology research and development, study a "Data Processing Zone" concept, and support I.T. and telecommunications services.

4. Revising laws and regulations which obstruct the development and use of I.T. and communications.

5. Restructuring the telecommunications sector and its publicly owned enterprises.

Thailand's central planning body is the National Economic and Social Development Board (NESDB). Its work is to formulate National Five-Year Economic and Social Development Plans and annual development plans, to study, analyze, and recommend solutions to development opportunities, to align development projects with the National Plan before implementation, to coordinate programme and project implementation in accordance with policies declared in the Plan, to monitor and evaluate development programmes and projects, and to facilitate communication [17].

The NESDB technology policy vision for the next five years focuses on human resources, technological research and development, technology transfer from foreign sources, and telecommunications infrastructure.

5.2 DEMAND ISSUES IN THAILAND

The more recent I.T.-linked institutions include the National Computer Committee (NCC) formed in 1984 and the National Electronics and Computer Technology Centre (NECTEC) formed in 1986. These two bodies have had very different development impacts. The National Computer Committee (NCC) is under the Bureau of the Budget. The cabinet established the NCC to scrutinize requests to purchase and use computers

in 1984. It has served to control, rather than to promote, computer use by public agencies. NCC has no permanent staff and relies on expertise from government agencies. This slows the approval process. Although NCC recently liberalized its controls, public sector computerization has been slow, while interagency systems or efforts at data integration are still unusual [18].

The National Electronics and Computer Technology Centre (NECTEC) mission is to develop technological capabilities in electronic and computer technologies; support the electronics and computer industry of the country; accelerate the computerization of Thai society in order to improve efficiency and productivity; promote research and development, and support industrial promotion and international competitiveness of Thai products. NECTEC, the bridge supporting the development and transfer of I.T. to local industry, has several small-scale successes to its credit.

In Thailand, it is the private sector (using the media) which most strongly influences public behavior and opinions about new technology. Individuals and organizations rapidly adopted I.T. tools even though the unique Thai language character set was not compatible with imported computer display and output devices. Researchers who studied these problems designed tools to support Thai language applications. Two well-known Thai language research products are Wor Tor Tor and the Thai Kernel System.

The Wor Tor Tor Thai system stems from a NECTEC project to develop an application programming interface for Thai system developers. It works with standard displays under the MS-DOS and UNIX systems. The Thai Kernel System (TKS) provides Thai application packages for general use. Currently available TKS packages include a Thai word processor, spread sheet, database and presentation graphics. Both were developed in local universities with MOSTE support [19].

5.3 PUBLIC SECTOR COMPUTERIZATION

Prior to the microcomputer boom, only large government offices in Thailand used computers, mostly for financial data processing and engineering computation, while public utilities used computers to print bills. Computer use expanded very rapidly with the advent of microcomputers, and some government offices are building new systems. For example, the Ministry of Interior completed a population registration project that won the 1990 Smithsonian Award for outstanding computer projects. The office of the Prime Minister uses image processing to track all cabinet resolutions, and plans to link the mainframes of four different ministries via a new wide area network [20].

The government relies on four bodies to plan and implement different public administration information systems. These are the Committees (a) on National Management Information System, (b) National Geographic Information System, (c) National Document Information System, and (d) the recently established National Telecommunications System and Information Technology Development. Although the government tasked the members to produce useful guidance and practical systems, the committees are moving slowly [21].

5.4 PRIVATE SECTOR INVOLVEMENT

In Thailand, the private sector and the government jointly promote and accelerate the process and progress of economic development. A growing awareness of common responsibility in the development process has expanded this cooperation, as increased private sector representation and participation in development projects demonstrates. The presence of major computer vendors [IBM, SAHAVIRIYA, etc.] and of the telecommunications services in support of industrial producers, international banks, and the multinationals is a factor in the development of the information technology community. Professionals from vendor organizations and multinationals form the core of key I.T. organizations such as the Computer Business Committee of Thailand.

5.5 INCENTIVE AND CONSTRAINTS

The Board of Investment (BOI) seeks investment from overseas, and has the power to grant tax exemptions and other privileges. To protect jobs for Thais, the use of foreign technicians and experts is controlled. Work permits can be obtained, but delays are commonplace.

Most large companies and industries in electronics and telecommunications manufacturing are foreign-owned or multinational enterprises. They rely on overseas offices to monitor technology development and to introduce any innovations. Many are export oriented and thus do not respond to Thailand's domestic needs. Others engage only on the finishing and assembly of imported

components, which limits the need for advanced I.T. capabilities.

5.6 TELECOMMUNICATIONS

The Telephone Organization of Thailand (TOT) and the Communications Authority of Thailand (CAT), state-owned monopolies, share responsibility for telecommunications services. TOT provides domestic, and CAT international service. Shortages of funds for expansion and limits on foreign exchange borrowing have limited investment, leading to a high level of unmet demand for basic telephone services, reduced quality of service to existing subscribers, and a lack of advanced services for business users. There are now only 1.8 million telephone lines, or 3 lines per 100 citizens, and an imbalance in the urban and rural distribution of service [22]. Radio-based services such as cellular mobile, radio telephone and paging service are growing, and help to offset the shortage of land-lines. The Seventh Plan aims at 5-6 million lines by 1997, or 10 telephone lines per 100 citizens [23].

5.7 R&D IN TECHNOLOGY

Because investment in R&D is only 0.1% of total investment, public funding of R&D is highly leveraged [24]. I.T. research in Thailand originated with NECTEC, which establishes R&D centers in target areas, provides funds for R&D work, industrial product development, and for researchers in universities and companies. NECTEC enables technological cooperation via tripartite arrangements linking NECTEC resources with users (local manufacturers) and researchers (at Thai universities). NECTEC will soon be merged with the Science and Technology Development Board [25].

5.8 SKILLED TECHNICAL MANPOWER

While I.T.-based industries need skilled labour, engineers, technicians, and I.T. specialists, these are in short supply. University output of engineering and technical manpower is inadequate across all sectors, particularly in data processing. The shortage is chronic in government departments and state enterprises. Although in 1987 9.1% of all employment was classified in S&T-related occupations, only about one-fourth had any secondary education. The low proportion of students entering and completing secondary school contributes to a scarcity of quality graduates[26].

The Seventh Plan targets science and technology manpower, technology transfers through foreign investments, and basic services in science and technology. Human resources development is one of its major targets [27].

5.9 TRAINING AND EDUCATION

Training programs offered by the private sector tend to focus on the application of products, while those organized by the public sector are resource-limited. Many larger organizations (banks, MNC's and high-technology industries, and technology-based state enterprises such as the TOT) provide internal training. Overseas training may be the only viable source for smaller private firms.

6.0 COMPARISON AND ANALYSIS

Singapore, with the time-critical but clear task to maintain its international competitiveness, was able to focus on a few critical issues, mobilize the needed political, financial, and economic resources, and build the organizational capacity to address those issues. Within the five years from 1981 to 1986, Singapore advanced from a nation with a shortage of I.T. resources to one which could integrate its I.T. capacity into its national economic plan. By 1991, Singapore firms were exporting branded software in direct competition with US and European producers, while the domestic I.T. infrastructure was so advanced that it was becoming a model for other nations in the region.

In contrast, Thailand still lacks clear Information Technology policy. For example, telecommunications development is not linked to the nation's electronic equipment manufacturing industry. Neither market nor technological information on telecommunications and electronics are available, and emerging information technology around the world cannot be adequately monitored. Another weakness is the lack of a framework for I.T. policy. Driven only by the private sector, the new technology is diffusing rapidly throughout urban Thai society, but providing few public benefits. The public sector could take a leadership role to use information technology to support national development, but the policies which are required have not been clearly articulated to date.

In both countries, an inhibiting factor for future I.T. development is the unwillingness of the local private sector to invest in research and

development, and the resulting weak linkages between the university research community and industry. While the private sector stands to gain most from local I.T. capability, they have been little involved in research work being carried out in the universities and the polytechnics. In Singapore, this gap was caused primarily by a lack of post-graduate programs and a very strong emphasis on teaching. Singapore overcame this problem by providing large subsidies to research projects and appointing prominent business leaders to serve on the governing boards of research institutes, while slowly building up its post-graduate programs. Thailand focused on developing a local market for contract research to be carried out by its more mature post-graduate centres.

7.0 RECOMMENDATIONS

The primary lesson from Singapore is that a clear and comprehensive I.T. policy helps in coordinating general industrial policies, S&T policies, manpower development programs, and telecommunications plans. Development of such policy must involve the public sector (at the inter-ministerial level) and large private sector organizations which can realign their resources to support the plan. As technical inputs will be needed, qualified experts should also be retained. But strategic technology and industrial development policies must be in harmony with other policies. Information technology can play an integrating role for technology, industry, social, and development policy. As a first step, the following is suggested as the agenda for national I.T. policy formulation:

7.1 NATIONAL I.T. MANPOWER RESOURCES

Manpower is and will continue to be the limiting factor. Thailand must invest now and develop professionals who are not only able to deal with technological change, but capable of helping firms exploit I.T. for productivity and competitive advantage. The government should increase university and technical school output, and provide incentives to encourage in-service training. These scarce human resources must be shared between the public and private sector to enable the efficient interchange of information. The public sector might also serve as a training ground and provide a pool of experienced technical professionals and managers to industry.

7.2 ORGANIZATIONAL CULTURE FOR I.T. USE

The transition to an information-based economy will require massive changes in organizational culture. In order for these new forms to be adopted, the value of I.T. must be recognized. Public sector agencies must demonstrate the value of I.T., and seek opportunities to prepare workers, managers at all levels, and policy makers for the information era. The schools and ministries most closely linked to industry are the logical initial target in Thailand.

7.3 DATA COMMUNICATIONS INFRASTRUCTURE

The economic value of information is greatest when it can be used as a substitute for physical activities. High-speed data highways will be needed to link public sector agencies, first with each other, then with the private sector. The emergence of mature ISDN technology during the past decade greatly simplifies this task.

7.4 PUBLIC DATA RESOURCE MANAGEMENT

The data highways will be useless unless public information about people, institutions, and physical resources is accurate, properly safeguarded, and well-managed. The design of the public database and the management of public information may be the most challenging of the technical tasks which lie ahead.

7.5 LINKING I.T. AND DEVELOPMENT PLANS

The desired relationships between public agencies, between these agencies and the public, and between the public and the private sector must be clearly defined. This is the strategic context for tactical decisions: Which public sector functions to automate? Which data to share? What data highways to build? These decisions must be linked to national policy, which must in turn reflect national development plans.

7.6 INFORMATION RESOURCE POLICY

To influence the long-term commitments which will be required to implement national I.T. plans, I.T. policy leadership must have solid credibility in both the private and public sector, and with different functions in the public sector. It is essential that these key players are not only involved with, but committed to the process.

Telecommunications in Local Municipal Governments

By:
Mack Schwing
Jonathan Dharmapalan
Padraic H. Riley
Deloitte & Touche

Effective telecommunications is becoming more and more important to local city and county governments in their increasingly difficult job of providing cost effective services to their constituents. Voice and data services within government and between government agencies and their clients are key operations and must be effectively managed and controlled.

Managing telecommunications is a major challenge facing local governments today. As the need for distributed processing grows and the dependance on a centralized mainframe located in a data center diminishes, these organizations are looking to creative solutions to meet telecommunications needs. This is further complicated by the organizational autonomy within local governments. In addition, the general public (constituents) are looking to the government for increased services in the form of information. Information that was once tied up in bureaucracy and paperwork is now being demanded on-line.

To meet this challenge, local governments are beginning to take a variety of steps in managing telecommunications. In this paper we have discussed some of the factors that make this a valuable but challenging task.

Introduction

Telecommunication in local municipal governments is critical to their overall operations. The telecommunication function is often provided and administered by several different agencies within most local municipalities. Often unique resources available only to municipalities are under utilized in providing telecommunication service. A comprehensive look at local government telecommunications helps in the development of a plan and the leveraging of the municipality's assets. As a result local governments can improve telecommunications services, reduce spiraling costs and even provide some revenue generating services.

ORGANIZATIONAL CHALLENGES

Developing an effective and flexible telecommunications system is a formidable challenge for any organization. While local governments have some unique advantages in this area, they also have certain disadvantages. These unique
advantages and disadvantages may not apply to all local governments, but they have emerged often enough in our analyses that they are worth discussing. Unique advantages to local governments include:

- Assets that enhance local government telecommunications capabilities
- Experienced, trained personnel
- Access to Right of Way
- Facilities and Buildings

Some of the disadvantages facing local governments are:

- Lack of awareness concerning the importance of telecommunications
- Failure to coordinate telecommunications systems and their development
- Inefficient use of telecommunications expertise
- Absence of a telecommunications master plan

ADVANTAGES AND DISADVANTAGES TO TELECOMMUNICATIONS DEVELOPMENT IN LOCAL GOVERNMENTS

Assets that enhance local government telecommunications capabilities

Local Governments are in a unique position as telecommunications users, despite some inherent disadvantages discussed above. Cities and counties have access to many assets within their jurisdiction that could be exploited to enhance their telecommunications capabilities. Unlike most organizations, these local governments are not entirely dependent on their vendors for telecommunications facilities and are frequently capable of providing most of their own services. Local governments can use some of these assets to not only reduce telecommunications costs but also to improve the services available to them.

Experienced, trained personnel

Many local governments have developed an experienced base of telecommunications specialists. This expertise is frequently deployed throughout the various departments in the government. Much is to be gained if this expertise is properly coordinated either through a coordinated management system or through consolidation into one organization.

Access to 'Right of Way'

Another valuable resource that is often ignored is a local government's access to local *right of way* conduits. Historically these *right of way* paths along streets or through government owned or controlled property have been used for a variety of purposes including electrical power grids, traffic light systems, fire alarm systems, and sewer-water systems. Today with the availability of fiber optic cabling technology, requiring very little conduit space, it is possible to use these *right of way* conduits for telecommunications systems. This is especially viable since fiber optic systems have become an inexpensive, highly reliable, alternative for high bandwidth communications requirements.

Access to *right-of-way* enables the Municipality to install and use telecommunications facilities at minimal expense and effort. Thus, the Municipality can have access to services not commonly available to other users.

Facilities and Buildings

Local governments also have control of many of the buildings and facilities in which the various departments are housed. As a result, the installation and maintenance of private telecommunications systems such as PBXs (in basement facilities), radio transmitters, and microwave towers (on building roof tops) becomes very possible. This environment makes it possible for local governments to deploy and manage their own telecommunications systems and provide most of the services required by the users.

Local governments also have many intrinsic disadvantages that have to be taken into consideration.

Lack of Awareness

There is a lack of awareness at senior administration levels within the government environment as to the critical importance of telecommunications. This problem is founded on the perception of telecommunications as a back-office function, and it persists both in the user community and the management/political hierarchy. Lack of awareness frequently translates into a lack of funding support for telecommunications.

Failure to Coordinate Telecommunications Systems and Development

The failure to coordinate telecommunications services is rooted in the fact that telecommunications is managed by many different departments within a municipality. For example most telecommunications expenditures tend to be spent to meet immediate requirements. Services are bought from vendors on an as-needed basis by the various departments. However these purchases are not coordinated and the municipalities buying power is not taken advantage of. Furthermore these systems tend to be incompatible and counterproductive in the long run. If properly coordinated through purchasing policies and technical standards it is possible to purchase and install communications systems that would be both compatible and cost effective in the long run. Organizations with telecommunications responsibility have to develop the coordination and the foresight necessary to implement systems that become a part of the entire municipality's telecommunications infrastructure.

Ineffective Use of Telecommunications Expertise

Much of the expertise in telecommunications is distributed throughout the many departments of local government. Individuals in each of these departments tend manage towards the needs of only that department. Furthermore the municipality as a whole does not receive the benefit of their expertise.

Absence of a Telecommunications Master Plan

Most of the issues discussed above could be addressed by developing a telecommunications Master Plan. Many local governments do not have a properly formulated plan that addresses telecommunications. This again may be the result of a distributed telecommunications management structure. No central organization is responsible for telecommunications planning. As a result, the government's ability to grow its telecommunications capabilities becomes limited.

A considerable amount of effort and activity is expended in dealing with day to day maintenance and management problems while the long term planning requirements go forgotten. As many of their private sector counterparts are learning, telecommunications planning is a vital and valuable activity. In fact, a properly formulated telecommunications plan helps focus day to day activity while building towards a growing municipal infrastructure.

STRUCTURAL CHALLENGES

These comments are based on our analyses of the municipalities of the City and County of Honolulu, City and County of San Francisco and the County of San Mateo.

Multiple Organizations / Departments and Entities

By the nature of local municipal governments they are divided into several branches to preserve the separation of legislative powers and be

responsive to their constituents. This creates the Administrative, Legislative and Executive branches of government including a public safety organization. Each arm of the municipality has different telecommunications needs and because of the separation of powers may develop and support their own telecommunication systems.

Many Organizations Provide Telecommunications

In the municipalities we studies, there are several agencies that manage and provide telecommunication services. Generally these agencies have responsibilities for other functions besides telecommunications:

- Electrical Systems - Department of Electricity
- Data Systems - Department of Data Systems
- Building / Facilities - Buildings Department
- Public Safety - Police, Fire, Ambulance etc.

Due to their expertise in these fields, or in the case of Public Safety, due to the extraordinary need for telecommunication services these organizations have historically managed some portion of the municipality's telecommunications system.

Department of Electricity - The agency responsibility for electrical systems has historically provided electrical services including wiring and electrical system maintenance. Since telecommunications systems also require some similar skills, the department of electricity has inherited some of the responsibility for telecommunications.

Department of Data Systems - The agency responsible for data systems has the primary responsibility of providing data processing and data communications services to the other municipal departments Although data processing requirements have always been high, data communications requirements have been minimal up until recent years. However, as some data-related applications, such as Geographical Information Systems (GIS) and Database programs, have increased the demand on data transmission these departments have taken on more responsibility for telecommunications. With the addition of new applications and the growth of PC based systems, the need for data communications facilities will increase significantly and the data systems departments will take on an even greater role in telecommunications management.

An area that will be especially impacted is the Local Area Network (LAN) interconnect capability. As many users migrate to PC based LAN systems, interdepartmental or interLAN communications will require significant telecommunications capabilities. The Data Systems department in many local governments are currently facing this challenge.

Building Department - Agencies responsible for the buildings and facilities often provide voice telecommunications services. Since telephone systems (voice communications) have historically been viewed as a facilities utility, Buildings departments have developed considerable expertise in this area. Today, voice communications is still the backbone of Municipal operations. Voice services often include the management of telephones, PBXs and Central office services. The Buildings department is also responsible for the installation of premises wiring, telephone sets, number assignments, moves, adds, and changes etc.

Public Safety - Public Safety agencies also support many of the local government's telecommunications services. Public safety requirements for telecommunications services are varied and complex. Emergency call-in, response, dispatch and patrol functions of public Safety agencies (ie: police, fire and ambulance) require significant telecommunications capabilities. These agencies have routinely provided and supported many of these systems including radio, paging, mobile communications and 911 emergency.

External Telecommunications Providers

In addition to Municipal departments that support telecommunications services, the following *external* entities also provide telecommunications services to the Municipal user community:

- Local/regional Telephone Company
- Long Distance Telephone Company
- State Governments
- Equipment Vendors

User Environment

To assess how voice and data telecommunications is used by local governments one has to understand the flow of information within the user environment of government entities. Generally the following six types of communications are present in a municipal environment:

Between Floors within a Building - Departments may occupy more than one floor in a building. Individuals in the same department on separate floors need to communicate with each other. In addition, individuals in separate departments need to be able to communicate with each other.

Between Physical Locations - There are many buildings and locations in a Municipality distributed over wide geography. The ability to communicate between physical locations is required in order for the departments and the Municipality to conduct its business.

Between Physical Locations and Vehicles - Public safety organizations, police, fire and ambulance dispatch centers must be able to communicate with their respective vehicles and stations for public safety and business needs. In addition, the Municipality has various agencies, such as Public Works, Parks, and Building which use this form of communication.

Between Physical Locations and Individuals - Examples include the usage of portable radios or cellular phones by Municipal employees to communicate with their dispatch or supervisory location.

Between Vehicles and Vehicles - This includes the public safety functions of police and fire vehicles along with the various Municipal maintenance or service vehicles.

Between Vehicles and Individuals - This includes the public safety functions of police and fire vehicles and personnel along with the various Municipal maintenance or service vehicles and personnel.

External Communications

Local governments have the need to communicate with many agencies outside the municipal government. Our review of a Municipality's external communications needs, determined that it maintain communication with the following:

- State Government
- The Judicial system
- Federal Government
- Business Community
- Public (Constituents)

A majority of the above current external communications is provided by voice transmission. However there are exceptions, for example in the City & County of Honolulu, Municipal environment specific external data connections include direct data links to both the State and the Judicial Computer Centers. External data links also exist for the NCIC application in San Francisco, New York, and Washington DC., NLETS Application in Phoenix, and the IBM Information Network (IIN) in San Francisco for the Commercial Drivers License Application (CDL).

More data-intensive external data interactions have been limited due to the unavailability of specific applications and the lack of a telecommunications structure to support them. These may include video conferencing, GIS data, land use, and other document storage and retrieval applications

TECHNOLOGICAL CHALLENGES

Increased need for internal communications

The Municipality has extensive voice, data, and radio networks to provide internal communications requirements. A majority of the current Municipal communications is voice transmission; however, there is a growing demand for data transmission between locations and vehicles. An example of the growing data demand can be illustrated by the Police Departments, which are evaluating the feasibility of providing patrol cars with mobile data terminals. In addition, there are many growing data applications, such as GIS, image processing, video conferencing, and Electronic Mail (E-mail) that are contributing to the growth in data transmission needs.

Voice and Data Transmission Requirements

Currently, the largest requirement for telecommunications support in the Municipal environment is for voice transmission. The largest need for data transmission is sending administrative data to departmental and end-user systems. Data transmission is also required to support personnel, accounting, inventory, and other administrative functions, tax administration, electronic messaging, and teleconferencing. Representative examples of functions generating telecommunications traffic are provided in the following paragraphs.

The fulfillment of the Municipal governmental responsibilities requires exchanges of data among departmental systems and end users. Data to be exchanged may consist of individual data elements, groups of cases, large data bases, or software files. The first two types of data need to be available on a real-time basis, while the large data bases and files may be downloaded during off-peak hours.

Departmental Data Transmission Requirements - Departmental systems download subsets of data from departmental data bases, maintain special purpose data bases, process information for local users, and provide access to large data bases.

The departmental requirements for the telecommunications architecture are as follows:

- Ability to connect workstations to local file servers or minicomputers and other Municipal common applications via local networks
- Ability to retrieve data from other systems
- Ability to transfer files between Municipal systems and departmental systems

End-User Data Transmission Requirements - End users maintain a variety of programs designed to help perform special jobs, such as auditing, budget tracking, and report writing. End users will need to retrieve data on departmental computers and send data to other users and shared output devices, such as printers and file servers.

Administrative Requirements - Estimates are that administrative functions may generate at least 20 to 30 percent of the total telecommunications requirements. These functions include personnel actions and payroll, inventory and supplies, procurement, travel and training records, and forms distribution. Some bookkeeping records are sent as file transfers for batch update of files, but on-line inquiries require interactive telecommunications among all levels of the Municipal offices. Other administrative functions that must be supported are Office Automation (including word processing, spreadsheets, data bases, graphics, and project management) and

entity-wide electronic mail services.

Data Traffic Volume - The largest volume of data telecommunications occurs on the local networks as minicomputers, file servers, and workstations exchange data throughout the day. The largest file transfers occur between departmental systems.

Image Transmission Requirements- Images are a special type of data. A digital image/optical disk storage system is a process of scanning documents, compressing the resulting bit streams by deleting blanks and repeated characters, and storing the images temporarily on magnetic disk and then permanently on optical disk or similar media. The data images can be retrieved at will from a central file, and transmitted over telecommunications lines, as file transfers, to a remote workstation for viewing.

The impact on telecommunications due to digital image storage and retrieval is anticipated to be noticeable despite the advent of compression techniques and the ability to transfer files to a local processor during off-peak periods, using the same network paths and protocols provided for character data. Image transmission would most likely use existing network paths but would require greater capacity than is currently available.

Video Requirements - Video requirements are expected to become more prevalent, as commercial video services become more cost-effective. For example assuming such services are proven cost-effective, video teleconferencing will probably be required by municipalities for providing interaction within the current core of municipal offices.

Large Informational Data Bases

If municipal governments are viewed as large repositories of data, then the automation of the retrieval and dissemination of the data would provide increased efficiencies. These efficiencies would allow the municipalities to provide a higher level of service and support increased work loads with out the addition of personnel or other expensive resources.

Municipal governments maintain large data repositories of information which include:

- Hearing / Meeting transcripts
- Tax assessment information
- Title search information
- Permit information
- Registration information
- Geographical Information
- Legal information
- Community Service information

Information Access as a Revenue Generator

These informational data bases are also of value to the general public and to the local business and legal communities. This information becomes useful if it is accessible electronically. As such, municipalities could potentially provide this information at a nominal charge to interested parties.

For example, the local legal community would have interest in accessing court calendars over an electronic access network. Other information access examples would include, public access to tax information, real estate industry access to title information, tourist access to calendar events etc.

Providing access to this information translates to direct revenue to local governments. This revenue could be applied to further improve telecommunications capabilities.

CONCLUSION

As discussed in this article local governments will have a significant challenge ahead of them if they are to keep up with telecommunications technology and demand.

Municipalities need to recognize that there will be unprecedented growth in telecommunications requirements. This will be as a result of internal information exchange and external interfaces to meet public demand for information. To date this information demand has been partly stemmed by paperwork and the slow processing of requests. As the common public becomes more computer literate the demand for electronic information will grow exponentially. This demand could range from title searches to requests for transcripts of recent hearings etc. Municipalities have to be prepared to deal with the telecommunications impact of such demand and eventual usage by their constituency.

To meet the demands for the future, it is important that local governments take the challenges discussed in this article into consideration while developing a management strategy for telecommunications and meeting further informational needs. Some of the steps necessary to arrive at a workable solution include:

- Develop a telecommunications master plan
- Develop workable standards for networking
- Coordinate telecommunications related activity throughout the organization
- Leverage the installed base of facilities, equipment and services.
- Develop and enhance the existing telecommunications expertise within the different organizations.
- Increase awareness within the user community and the management hierarchy.
- Plan telecommunications deployment as a long term investment and build upon the infrastructure.
- Provide access to public information and potentially generate revenue.

These steps are a precursor to arriving at a manageable solution. It should be recognized,

based on our analysis of the City & County of Honolulu, the City & County of San Francisco and the County of San Mateo, that municipal governments are a complex environment, each with its own special needs and idiosyncrasies. As such, each environment has to be assessed separately and an appropriate plan to deal with telecommunications has to be developed. If properly planned and implemented, both the Municipality and its constituents stand to gain significantly in the long run.

We would like to thank our clients at the City and County of Honolulu, Hawaii, the City and County of San Francisco, California, and the County of San Mateo, California for their support in preparing this paper. Ideas expressed in this paper are those of the authors and do not represent views of the respective government agencies.

INFORMATION TECHNOLOGY AS AN EMERGING PARAMETER IN REGIONAL PLANNING

by

George E. Darby, J.D., M.B.A.

Law Offices of George E. Darby
and
President, Eidetic Technology, Inc.

Information technology products and services are the sinew and tendon of modern commerce. Government planners and academics have characterized the deployment of information technology products and services, and the resultant information economies, as the advent of the information society. Yet, when one examines the literature of urban and regional planning, there are few, if any, references to information technology as a planning parameter. While planning for information technology products and services may remain a silent variable in industrialized countries, for those nations without an industrial base from which to create an information society, methodical consideration of how to optimize information technology resources is critical. To advance the theory that there should be more consideration of information technology in planning the leap from pre-industrial to post-industrial society in such countries, the author discusses one perspective on the use of information technology as a parameter in regional planning.

I. INTRODUCTION

How should the work and residential requirements of service and information workers for information technology infrastructure shape urban and regional planning? U.S. and Japanese literature is voluminous in its discussion of the information, or informationalized, society (in Japanese: *joho shakai*, *johoka shakai*, or even *enha joho shakai*), but little has been published on information technology as a parameter in urban and regional planning. Although the literature concerning intelligent buildings and technology parks is somewhat related, these articles focus primarily on the building layout, the sizing of conduits, surveillance and security systems, and other architectural topics. Between the subterranean discussion of conduits and the stratospheric discussion of the information society, an important policy issue has gone begging: what information technology products and services should be developed to promote economic development of a city or region in non-industrialized nations?

It is understandable that information technology should be a silent variable in urban and regional planning within industrialized countries: the industrial sector in these countries gave birth to the information economy. Financial, marketing, and management information processing has supported the purchase of successive generations of computer, voice, image/video, LAN, WAN, and now MAN and multimedia products and services. Roads, water, wastewater, conduits for electricity and telecom, but not information technology per se, have been the regional planning design issues. Although market forces in industrialized countries may obviate the need for governmental or developer planning for information technology products and services, such is not the case in non-industrialized regions.

Non-industrialized nations are usually characterized by fuel and other resource scarcity and few hard currency exports. Many non-industrialized nations have diminishing, or very cyclical, agricultural export earnings, may desire (or are forced by circumstances) to "bypass" significant industrialization, and look to a service economy, especially tourism, for economic development. Although recognition of the financial and environmental advantages of service economies is widespread, planners working for governments and developers usually fail to recognize that a service economy is by definition an information economy and is therefore based on information technology products and services. Such planners are unaware that successful development of a service economy cannot occur without concomitant planning and development of information technology products and services.

The premise of this paper is that planning regional development in non-industrialized countries must go beyond consideration of cable plant, central offices, cable landings, and earth stations; planning a service economy must include the description of the information services to be provided and the hardware and software on which these services will be created and grown.

II. TOURISM AS THE TEST CASE

Most, if not all, Pacific Island nations look to tourism as the best, if not the only, means of substantial economic development. There are few alternatives. In some Pacific nations, fisheries provide several million U.S. dollars a year of income. Usually, this means selling fishing rights to foreign fishing fleets, however, not a domestic fishing industry. The fresh fish, cut flower, aquarium fish, or other high margin industry languishes in many Pacific nations for lack of a reliable means of transportation of perishable products to markets in industrialized countries. Tourism, and the reliable air transport that tourism brings, solve two major problems: bringing hard currency into the country through tourists' spending, and exporting perishables to foreign markets.

Tourism to Pacific Island nations (as well as to many rural areas of Asia) has traditionally been the domain of the adventurous individuals, known in the travel industry as free independent travelers ("FIT"). FITs will tolerate lack of (or seek to avoid) telephone and fax service, television programming, day tours, Western-style hotel rooms, reliable air service schedules, and other services that less adventurous travelers, such as group inclusive travelers ("GIT"), require. As a rule, FITs are fewer, spend less, and arrive with less predictability than GITs. Obviously, Pacific Island nations must attract GITs to build service economies. Attracting and retaining a GIT visitor base has many implications for information technology products and services, however. These implications can be broadly categorized as guest communications, supplier communications, and intermediary communications.

Guest communications start with a guest's inevitable call home after checking into accommodations (hotel, bed & breakfast, etc., generally called the "property"). This means international direct dialing from the guest room, or at least from the property. A phone booth off the property is not acceptable to the many GITs who venture off the property only with the tour group. In addition to voice communications, GIT escorts desire fax service on the property, especially if the time zone of the property is very different from the home country time zone. Business guests, even during leisure travel, also seek fax service and, increasingly, a second line in the guest room for modem or fax/modem use. If a property wishes to market itself as more than leisure traveler accommodations, a quantum leap in information technology is required. Even small business meetings, such as management retreats, commercial seminars, and smaller conferences, attract guests who are accustomed to sophisticated information technology services, such as voice processing, PC rentals, A/V systems, e-mail and online services, and videoconferencing.

Supplier communications are basically of two types: property procurement related and guest support. Property procurement related communications involve obtaining supplies and labor to support property operations. Guest support communications involve dialogs between guests and off-property suppliers of consumer products (especially souvenirs), entertainment, day tours, and dining. "Supplier communications" refers to the fact that suppliers, including local businesses near the property, must have telephones. This is not always the case in non-industrialized countries.

Intermediary communications are primarily reservations systems, preferably computerized reservations systems. Although international airlines all use computerized reservations systems, most property reservations systems in non-industrialized countries are still limited to mail, telephone, and, increasingly, fax. Intermediaries, such as travel agents and tour packagers, must deal directly with properties, airlines, and other travel service suppliers. By dealing with a travel agent or other intermediary, a GIT traveler is screened from the frustrations of non-computerized reservations systems.

The travel agent, however, may steer clientele toward properties and suppliers that have computerized reservations systems, however, to avoid spending inordinate time arranging and rearranging an itinerary by phone and fax. The rapidity with which properties and other suppliers can be checked for availability, reservations made, and confirmations received are probably the highest priority guiding travel agent behavior. Ceteris paribus, only if a client insists on using a supplier without a computerized reservation system will a travel agent do so; in such cases, the agent has a defense if the "confirmed reservation" is otherwise.

Also included in intermediary communications are marketing products, especially audiovisual programs, produced by property owners, local suppliers, tourism promotion agencies, and others for use by intermediaries in attracting travelers. Audiovisual products for intermediary communications now include multimedia presentations on laserdisk and CD-ROM.

III. FUNDING I.T. PROJECTS

Building a tourism-based economy requires planning and providing a basic level of information technology services for guest, supplier, and intermediary communications. Competing for meetings and convention business requires a level of information technology sophistication equal to that in the U.S., Japan, and Europe. Generally speaking, ministers of tourism in non-industrialized nations also have other portfolios that usually present higher priorities for immediate use of available hard currency than information technology. Even if these ministers, their peers in cabinet, and the prime minister appreciate and plan for the type and amount of information technology products and services required for economic development, there are often no funds to purchase such products and services.

This author suggests that the funding of information technology infrastructure, products, and services can be accomplished as part of an expanded development agreement with parties proposing to construct hotel properties or other real property improvements. In such a development

agreement, the host government would agree to a lower revenue to government (whether by tax rate, commissions, lease rent, etc.) in exchange for the developer's installation of "oversized" computer and telecom equipment and an off-property VSAT earth station and remote telecom switch. The "normal" capacity of the computer and telecom equipment would be used for basic guest communications and a computerized reservations system for the property. The "extra" capacity in the computer and telecom equipment would be used for supplier communications. Under the development agreement, the developer would construct cable plant connecting local suppliers with the remote telecom switch. International communications would be via digital VSAT services. Either government or contract staff would maintain the VSAT equipment and remote telephone switch. If the developer were not building hotel or accommodations, the remote telephone switch would serve nearby hotel or other properties in addition to suppliers.

Using this approach, digital communications could be provided to properties and basic telephone service to local suppliers (and residences). Digital communications hardware would permit not only the basic services, but would avoid investment in analog equipment and enable videoconferencing and other business guest services equal to those in the industrialized countries.

A CRITIQUE OF AMERICAN INFRASTRUCTURE NETWORK PROJECTS TO GUIDE EFFORTS TO SUPPORT SOCIAL VALUES THROUGH NETWORKING

Thomas I. M. Ho
Carnegie Mellon University
Pittsburgh, Pennsylvania USA

Kai Sung
National Central University
Chung-Li, TAIWAN, Republic of China

ABSTRACT

During the last several years, the American telecommunications landscape has blossomed with comprehensive computing and/or communications infrastructures created as a result of the partnership between the public, i.e. government, and private, i.e. business, sectors. This paper will highlight social implications as a follow-up to the authors' previous work. As a result, it is expected that others, namely other state and provincial governments as well as other countries, can learn from these experiences so that their benefits can be replicated at lower financial and political cost and in more timely fashion.

INTRODUCTION

There is little doubt that increased attention to interpersonal relationships, increased communication, and increased use of consensus decision making are current trends in business.

Evolving trends in organizational structure have ramifications for communication.

As the role of communication expands, the role of information technology in promoting communication is fostering experimentation in organizing work and in management practices. (Butera & Bartezzaghi, 1983; Short, Williams, and Christie, 1976) As an example of a new way of organizing work, tele-commuting no longer requires people to go to an office to go to work. (Cross & Raizman, 1986)

INFRASTRUCTURE NETWORKS

An infrastructure network is a telecommunications network that provides basic communication services on which public, e.g. government, or private, e.g. corporation, organizations depend for their survival. Mears (1974) defines a communication network as "the interaction required by a **group** to accomplish a task." Mears (1974, p. 71) states:

> An organization's effectiveness depends upon the performance of numerous small **groups** which function and interact within the overall organizational system. Since the activity of a small group depends to a great extent upon its information flow, the **communications** act has been studied as a means of influencing efficiency.

An infrastructure network is distinguished from any ordinary communications facility because it is both pervasive and comprehensive to promote group participation! An infrastructure network provides the foundation upon which value-added (beyond merely transport and switching) information services can be exploited for competitive advantage or for service improvements. For example, tele-commuting requires considerable value-added services such as office automation to support calendaring and other functions necessary to support a mobile work force. Electronic mail is another value-added service that requires an infrastructure network to provide connectivity and accessibility across the twin barriers of time and distance. (Rice & Case, 1983)

Case studies have demonstrated that most benefits derived from information technology improve intragroup communications. (Strassman, 1985, p. 43)

However, a critical mass of connected workstations must be achieved to enable a group to try new ways of organizing work! It is necessary to construct networks of considerable scale in order to achieve major improvements in office communications.

An infrastructure network consolidates the communications requirements of virtually all of the organization to achieve economies of scale. (Ho, 1987) An infrastructure network complements the public telecommunications network by providing a more robust and complete infrastructure in either the public (Ho, 1987) or private (Estrin, 1987) arena. As Kling and Scacchi (1982) point out, good infrastructural resources are essential for the smooth deployment and routine operation of any information technology.

The pervasiveness and comprehensiveness of infrastructure networks enable powerful communication services such as:

1) Video communication is especially effective in motivating employees and in communicating social and organizational values.

The contribution of videoconferencing to horizontal and diagonal communication that enable non-hierarchical links has been documented by Dutton, Fulk, and Steinfield. (1982) Furthermore, a variety of consensus-building activities that involve group decision-making were also reported.

Video communication consumes large amounts of communication capacity that require the robustness of infrastructure networks.

2) Gateways to other networks promote communication with other organizations so that one can gain access to other resources such as education provided by trade groups or third-party vendors.

The influence of gateways on communication patterns of people and organizations has been discussed by Estrin. (1987) Gateways are expensive to develop and to maintain so that they are most easily justified when they are shared by many users that are supported by an infrastructure network.

3) Value-added services include the variety of office automation tools such as electronic mail that will improve communications.

More powerful tools such as computerized conferencing (Hiltz & Turoff, 1978) that support group decision-making require even more communication capacity. Gordon Thompson (1972) has identified three criteria that characterize the communications revolution made possible by infrastructure networks:

1. It will ease the access to stored human experience.
2. It will increase the size of the *common communication space* shared by the communicants, and therefore increase the amount of shared information and interaction among them.
3. It will increase the ease with which new ideas can be developed and spread throughout a society.

Hiltz and Turoff (1978, pp. 469-472) have claimed that computerized conferencing ranks highest according to these criteria when compared against less robust communications alternatives, e.g. books, telephone, face-to-face, and TV.

Background

INTELENET

INTELENET (INdiana TELEcommunications NETwork) is an initiative of Indiana state government. INTELENET (Ho, 1987) merely provides transmission and switching services for Indiana government and education. INTELENET is an infrastructure network on which all other value-added networks would depend for basic transmission and switching services. As such an infrastructure, INTELENET is similar to the public switched network provided by common carriers. With respect to regulatory/policy issues and finance and economics, it differs from the public switched network. INTELENET is owned by GTE Telecom, an unregulated subsidiary of GTE, and leased by the INTELENET Commission, a body corporate and politic, created by Indiana state statute. The INTELENET Commission resells transmission and switching services to Indiana government and education as defined by the INTELENET statute.

NYSERNet

NYSERNet (New York State Education and Research Network) is the NSFNET's regional mid-level network serving New York education and business. NSFNET (Quarterman, 1991a & 1991b) is the main backbone network in the Internet. The Internet is the successor to the former ARPANET serving the U.S. government's Defense Research Projects Agency. The array of networks now consists of three tiers (Mandelbaum & Mandelbaum, 1991):

1. A national backbone network that connects supercomputer centers and the various regional wide area networks
2. Regional and supercomputer-consortia networks, e.g. NYSERNet, BARRNet (San Francisco Bay Area Regional Research Network), and SURANet (Southern Universities Research Association Network)
3. Campus networks, i.e. internal local area networks serving a single academic or industrial campus.

The first two tiers constitute NSFNET. NSFNET is not a network; it is an inter-network, i.e. a network of networks.

K-12 Networking

The phenomenon of providing Internet access to the K-12 (kindergarten through 12th grade) community provides exciting examples of infrastructure networks. The EDUCOM K-12 Networking Project (Clement, 1991) aims to link together primary and secondary education through computer-mediated communication networks. In this way, the project will develop network-using resources to support curriculum reform and institutional restructuring. EDUCOM can be contacted at:

The Consortium for School Networking represents a national effort to establish the "K-12 network" in the United States. Related efforts in Japan include the Association of Global Electronic Networking Educators:

Masahiko Nakauye

An example of a local initiative in K-12 networking is "Common Knowledge: Pittsburgh" to provide Internet access to all teachers and students in the Pittsburgh public schools and to begin to integrate this new technological resource into the existing school curriculum.

The history of this initiative goes back more than two years when Professor Robert (Bob) Carlitz of the University of Pittsburgh's Department of Physics and Astronomy began to investigate the possibility of extending Internet access to the K-12 community. In connection with this exploration, Bob created an Internet mailing list called KIDSNET that now reaches around the world.

As teachers in Pittsburgh have gained access to the Internet (mostly through the University of Pittsburgh), they have discovered resources such as the NASA Spacelink or the Cleveland Freenet or have established international exchanges with other classrooms worldwide. As we have worked to develop a project which can reach all teachers and students in the Pittsburgh public schools, we have made an effort to structure the project so as to maximize its potential classroom benefits. We are attempting to build a support network that has the breadth to reach all teachers and the depth to accommodate people at all stages of familiarity with this new technology.

Curriculum support will come from the existing mechanisms for developing and implementing the school district's curriculum. Among the projects that are currently being discussed are the following:

1. Industry tutors for students developing science projects
2. International exchanges with schools in Asia and Europe
3. Identification and cataloging of regional habitats including urban neighborhoods and city/state parks
4. An interactive library card catalog
5. Development of writing skills through exchanges of letters

Many of these activities are already taking place. All have the characteristic that they may be easily extended to involve children, teachers, and professionals outside of a given school - and even outside of Pittsburgh, Pennsylvania, or the United States. This extensibility is the greatest strength that the Internet has to offer.

There is another aspect of the Internet that is significant. Already, the Internet reaches all of the research universities in the United States, Europe, and Japan as well as hundreds of companies. As this connectivity increases, one will be able to tap some of the resources latent in these organizations. More people will become active in the schools by dropping in electronically for a little while every day. In a similar fashion, students will leave the confines of the classroom and make electronic visits to museums, libraries, businesses, and governments around the world.

There will be many concrete benefits that one can expect from such a network. In terms of educational issues, the following problems can be attacked:

1. Isolation: The current isolation of the classroom teacher would be largely reduced by such a network. Teachers could easily communicate with their peers, their supervisors, and experts in their fields of specialization.
2. Access to information: This need is most obvious in the sciences where entire disciplines are redefined in a decade or less. Nevertheless, it is relevant to all fields and to the general intellectual vitality of the teaching environment.
3. Equity: Network resources are **shared** resources. A network which reaches all schools carries all information that is made available on the network to all of these schools.

The Consortium for School Networking seeks to spread this phenomenon throughout the entire United States. Those states which choose to encourage the development of this activity will have the opportunity to establish themselves as leaders in this field. It is a field which knows no national boundaries so leadership in this field means leadership in a major international activity.

For this reason, the project seeks to build a sphere of "Common Knowledge." This phrase refers to both the idea of a shared body of information such as we would want our schools to teach our children. And it refers to the idea that we would want all people to share this information - that it should be common knowledge for everyone.

Information services initiatives

The removal of the information services ban on the Bell regional holding companies puts the spotlight on initiatives related to information services. Among these initiatives, Hawaii INC (Hawaii Information Network Corporation) encourages the creation of information providers. A "grass roots" effort to promote economic development and to improve quality of life through telecommunications and information technology is POINT 21 (Pittsburgh's Opportunity In New Telecommunications for the 21st century) that has conceived a Regional Information District to serve southwestern Pennsylvania.

The Regional Information District would provide a mechanism for businesses, schools, nonprofit groups, and governmental agencies to share information resources. The Regional Information District would benefit all participants. Specific instances would include the following:

* New information resources for the schools
* Improved workforce for businesses
* Efficient information delivery for governments
* Good environment for information-related businesses
* Model schools for the information age

Full implementation of the Regional Information District would involve network connections for all government agencies, businesses, nonprofit organizations, and schools in the region. Development of such an extensive network would take several years - perhaps until the end of the decade. In the near term, one could build upon existing networks and provide incentives for the extension and interconnection of these networks.

For example, take university networks and the Internet as a working model. Connect model school districts to the Internet and begin to develop educational materials through model projects. Allow businesses to connect to the Internet at low educational rates if these businesses agree to provide either mentors or some educational materials through their network connections.

Develop model projects involving nonprofit groups, e.g. libraries and museums. Fund these projects through grants developed in connection with the model school districts. Develop an agency, i.e. Regional Information District, to facilitate the networking of nonprofit groups. Nonprofits could contract with this agency for network services and advice. Funds raised through this mechanism could sustain the operation of the agency. Another agency could be established to guide the development of educational materials for the model school districts. This agency could be funded through grants which support the local model school districts and through paid services provided to other school districts around the country. The America 2000 program provides a mechanism of this sort which could be exploited to help fund this agency.

In this way, the community would gain first-hand experience in the delivery of information services as well as in the development of computer-based educational materials, two emerging industrial sectors.

OPPORTUNITIES FOR NEWLY-INDUSTRIALIZED NATIONS IN ASIA

In an earlier paper, we (Ho & Sung, 1990) claimed that infrastructure networks represent a vital opportunity for newly-industrialized nations in Asia. In these nations, through effective communication, social values related to the "group" will produce a better payoff. This payoff would result from the momentum and partnership experience generated by recent economic success. Also, the relatively smaller size of these nations would enable easier networking. Finally, as demonstrated by their success and as a result of their smaller scale, the ability of these nations to focus on what needs to be done will insure the wise investment of funds earned from economic success in projects that will guarantee future success.

We recommended the development of infrastructure networks including national and local networks as well as gateways (to other national networks) and other network, e.g. data bases, resources. The involvement of all constituencies, government and education as well as the private sector, will encourage experiments with information technology in organizing work and in management practices that incorporate social values.

Asian political-administrative traditions have stressed the desirability of harmony and consensus. A concern for consensus and values related to the group will result in a higher payoff through communication. Furthermore, the momentum and partnership experience achieved through recent economic success can be sustained through communication.

Just as the existence of comprehensive and pervasive infrastructure networks will encourage experiments with communications technology in organizing work and in management practices, these networks will encourage experiments in economic development and quality of life, e.g. educational reform.

Experiments in organizing work to change the concept of work

The impact of information technology on the social fabric of group life is discussed by Kling. (1984) The way in which work is becoming organized requires a new set of skills. (Bernstein, 1988) As companies change from old models of assembly-line production to Japanese-style work teams, employees will have to improve their ability to communicate.

One of the characteristics of a productive organization is that the way individuals are linked together is of greater importance than what any individual does in isolation. (Strassman, 1985, p. 23) Electronic mail encourages collaboration. For example, this paper was produced by communicating via Bitnet, the worldwide academic network (Fuchs, 1983), between the United States and Taiwan. Communicating across time zones and between remote locations creates new organizational opportunities for accomplishing work on a decentralized basis. (Strassman, 1985, p. 44)

Experiments in management practices that incorporate social values

Communications technology can enable the distribution of knowledge throughout an organization. This distribution can then manifest itself in terms of changes in organizational relationships since knowledge no longer remains exclusive among only a few individuals. The result is a more effective organization.

Replicating scarce knowledge can profoundly affect organizational structure and corporate culture. When scarce knowledge is more widely available, personnel at lower levels of the organization, rather than merely senior management, may more aggressively participate in decision-making.

SUMMARY

Networks are indeed capable of creating opportunities for experiments in organizing work and in management practices. These experiments can change the concept of work in ways that incorporate social values that emphasize teamwork. Teamwork is among the social values that have contributed significantly to the economic success of Asia's newly-industrialized nations. For these nations, infrastructure networks that are both pervasive and comprehensive in order to maximize group participation represent a genuine opportunity to capitalize on this situation. Furthermore, these networks can encourage experiments in economic development and quality of life.

INTERCONNECTING THE PACIFIC

ROBERT F. KELLEY, JR.
MANAGEMENT COMMUNICATIONS SERVICES

GEORGE J. BOUGHTON
UNIVERSITY OF GUAM

1. ABSTRACT

The global community is moving to a new era in telecommunications technology and utilization. The people of the Pacific Basin are being bypassed by these developments. It is the purpose of this paper to suggest a model by which the Pacific Islands can begin to participate in the telecommunications revolution. To facilitate the discussion of this model this paper has been organized into the following major sections: (1) Introduction; (2) An Alternative Regional Communications Service; (3) A Model Thin Route Network; (4) Implications of the Regional Network.

2. INTRODUCTION

At the turn of the twenty first century, the Pacific world stands on the threshold of a revolution. Developments in communications, shipping, transportation and production technology herald significant changes in nearly every aspect of the region's life. Several authors have begun to speak of a Pacific era in which the developed nations of the Pacific Rim will assume a leadership role of an increasingly cosmopolitan world society. (1)

Within this revolution, changes in telecommunications technology and computer utilization appear to be having the greatest initial impact. Access to information by countries, corporations and individuals is greater and more reliable than at any other time in humanity's experience. The ease with which information can be accessed and expanded presages cultural, economic and social changes in world society which may prove to be as significant as the Renaissance and the Industrial Revolution. (2)

The potential of these changes has been recognized by a variety of authors and scholars publishing in a variety of different forums and formats. It has led the United Nations to include the following article, number 19, within the Universal Declaration of Human Rights. (3)

> *"Everyone has the right to freedom of opinion and expression: this right includes the freedom to hold opinions without interference and to seek, receive and impart information and ideas through any media and regardless of frontiers."* (4)

Unfortunately, the twenty first century revolution is bypassing the people of the Pacific Basin. Instead of experiencing state of the art modernization of telecommunications service, the island nations of the Pacific have experienced a slow and inadequate expansion of their communications resources that severely handicaps their ability to participate in the modern world. Several significant reasons for this lack of development are: the remoteness of the region; its small population, inadequate infrastructure; lack of natural resources, and limited potential for economic development; the restrictive policies toward non indigenous communication services imposed by the governments of the region; the lack of interest in developing "thin route" areas on the part of carriers based in the nations of the Pacific Rim; and the tendency on the part of regional governments to view high long distance telecommunications tariffs as a necessity to help upgrade their domestic telecommunications systems and to feed development in other sectors of island society.

3. AN ALTERNATIVE REGIONAL COMMUNICATIONS SERVICE

It is the purpose of this paper to suggest an alternative to the present situation. This alternative envisions the creation of a regional telecommunications network that will link the Pacific Basin with an integrated voice, data and video communication services. Such a network will be designed to achieve two immediate goals.

1. It will provide intraisland links within the Basin. These links will allow the peoples and governments of the Pacific to communicate with each other more easily and less costly than has been possible in the past. Given the similarity of the region's cultural traditions and developmental problems, this sharing can help the region to strengthen common ties and cultivate more effective solutions to commonly experienced developmental problems.

2. The network will provide a direct interface for island users with international communications services. For the first time the peoples of the Pacific Basin will have open and equal access to the world's telecommunications resources. No longer will the region be viewed as a backwater cut off from world developments by its remoteness, low population density and lack of technological resources. Such a development will also aid the regions ability to begin solving its developmental problems by bringing the insights of other cultural, economic, political and social systems to bear on the island experience. In addition it will provide island users with a possibility for self enrichment undreamed of in past generations. Businesses locating in and tourists visiting the region will be provided with equivalent communications services to those available in the more developed nations of the Pacific Rim. This availability should encourage economic development and diversification within the region. By increasing the connectivity with the rest of the world, the Pacific Basin will also be able to buffer itself from those outside forces that have controlled its destiny for the past three centuries. For the first time in the modern era the region can begin to contemplate playing something other than a dependent role in world affairs. (5)

4. A MODEL THIN ROUTE NETWORK

The most reliable and cost effective solution to interconnecting the Pacific Basin is to develop a digital satellite network linking through a central hub, the various island nations to each other and the rest of the world. The hub will also provide a communications gateway to other international carriers.

This process was begun in 1986 when PCI Communications, Inc., a Guam based telecommunications company, created the Pacific Data Network, PACNET. This network presently links Guam, the Commonwealth of the Northern Mariana Islands, Hawaii, and the U.S. mainland. It uses existing satellite and where available, fiber optic channels to achieve this purpose. While PACNET does not presently provide communication, voice and video services to the other nations of the Pacific Basin. It does, however, provide a useful example for the establishment of a broader integrated digital communications network for the area. This model would also be applicable for other sparsely populated areas of the world.

An integrated digital network is designed to provide voice, data and video over common digital bearer circuits trunked to one or more gateways with applications provided by derived circuits on a demand or preassigned basis.

Compression will be used to reduce required bandwidth between each point on the regional network. At the gateway, the network will interface with other international carriers utilizing standard signaling and digital interfaces. By providing a variety of services to various global locations through a common gateway, maximum utilization of facilities will be realized.

The network gateway switch will be located so that most international calls through other transit carries will be terminated via cable facilities. Some international traffic and all regional traffic will necessitate a double satellite connection. While this is not an ideal situation, it does provide effective communication, provided digital echo cancelation is utilized. Double satellite toll connections are still standard and accepted in some international applications as well as many of Alaska's remote villages.

A data network utilizing packet switching or frame relay will provide a seamless interface with the other VAN's for international access as required by the users. The Network's seamlessness allows island users to access the major international networks in the same fashion and at similar prices to users in the more developed nations of the Pacific Rim.

International toll switched voice services will be provided on a fixed 16 Kbs Time Division Multiplexed channel and will be allocated on an as needed basis or maintained on a preassigned basis.

Voice packet options have been considered and found not to offer the required quality needed for public switched services. The routes in most Pacific islands will require too few derived circuits to gain a satisfactory multiplication through statistical compression. The cost of acquiring and maintaining a Full Mesh DAMA system with todays technology would not be economically viable for remote thin routes of the Pacific Basin.

The most satisfactory 16 Kbs voice quality currently available is obtained using a frequancy-domain hybrid coding technique known as Adaptive Transform Coding (ATC). At 16 Kbs, most users rate the voice quality as equal to a local call. In addition, ATC at 16 Kbs can satisfactorily pass in band data signals up tp 2400 Bps. (6)

A cost effective and readily available choice for Voice Data multiplexing equipment is the Clarity 8000 manufactured by Pacific Communications Science, Inc. In provides 4 Data Ports, supports up to 8 ATC voice cards and transparently supports 9.6 Group III fax transmission on the voice ports. Its largest drawback is the current lack of a digital interface supporting a DS1 connection between the Clarity and the telephone switching equipment requiring additional Analog-digital-analog conversions. It is expected that hardware updates will soon address this limitation.

Simplex point-to-multipoint broadcast services can be provided utilizing a 64 Kbs or 128 Kbs (if stereo) digital link and 7 Khz audio codecs. This service will have a superior quality to existing analog satellite services.

A 128 Kbs Duplex channel will be available through the network for scheduled assignment between any 2 points for providing a video conference channel. This channel should also be capable of operating at 112 Kbs for direct interface with the DDS services on other carriers. It will be to the regions advantage to agree on the video codec manufacture for regional use to avoid conversion costs as well as to be able to negotiate the most favorable prices.

Equipment Cost Example

Remote Site

Equipment	Estimated Cost
1. Small Switch for interfacing the local public switched network and the regional network	$10,000
2. Answer detection and supervision equip.(if answer detection in not provided by LEC)	$3,000
3. Voice compression equipt.(4 voice)	$14,000
4. Satellite modems (1 for each service)	$9,000 each
5. Solid State C band RF Transceiver	$25,000
6. 4.5 Meter C Band D-1 antenna (a)	$12,000
7. 7 Khz Audio Codec (b)	$7,000
8. Video Codec (c)	$25,000
9. Packet Switch Pad (d)	$10,000
10. Integrated UPS/Generator	$5,000
11. Test Equipment (e)	$20,000
TOTAL for Broadcast and Video (f)	**$158,000** *

(a) This includes a simple tracking mechanism
(b) This would cost $14,000 for a stereo service
(c) This is for a basic fixed camera system. Additional features will add to price
(d) This is needed only if Packet services are supported.
(f) Includes Spectrum analyzer, power meter and TIMS
(g) This price includes one modem for Switched voice, one modem for Broadcast reception and one modem for video conferencing.
* This does not include site or construction costs

Gateway Site

1. Toll Switch	$200,000
2. Voice compression equipt. (24 voice)	$60,000
3. Integrated frame relay, packet, circuit switch	$30,000
4. Satellite modems (1 for each service)	$9,000 each
5. C band RF Transceiver (300 watt)	$96,000
6. 9.1 Meter C Band D-2 antenna (a)	$140,000
7. 7 Khz Audio Codec (b)	$7,000
8. Video Codec (c)	$37,000
9. Packet Switch Node	$30,000
10. Integrated UPS/Generator	$15,000
11. Test Equipment (d)	$40,000
TOTAL For Toll, Data, Broadcast and Video (e)	$709,000 *

(a) G/T 31.7 dB/K at 20 degree elevation
(b) This figure will be $14,000 if stereo service
(c) This is for a basic video conferences system with movable cameras.
(d) Includes spectrum analyzer, power meter, TIMS, waveform monitor, oscilloscope and noise generator
(e) This price includes four modems for Switched Voice, one modem for Broadcast Transmission and one modem for Video Conferencing.
* This does not include site or construction costs

Intelsat has two tariffs that are suitable for use in the Pacific Basin for thin route traffic utilizing the network configuration described above. IBS service would be the best choice for all nonswitched voice applications, however, it is not permited for Public Switched Voice applications. The Intelsat IDR service does not permit the use of 4.5 meter antennas. Intelsat has recently approved digital communications on VISTA service allowing for small antennas at rates similar to IBS. This Digital VISTA service is ideal for switched voice and packet data (assuming packet data is transmitted on a low speed data channel of the digital voice compression equipment.)

Given the low density of communications traffic and the limited number of users within the Pacific Basin, the establishment of one regional network is an effective way to achieve an economy of scale. If each island state sets up its own independent service, the infrastructure and network management costs are significantly higher. These costs will be passed on to the individual and corporate users and will ultimately result in reduced usage. Reduced usage will require the remaining customers to bear even higher costs or it will force island governments, with limited financial resources, to subsidize communications service.

Similarly, the thin route nature of the Pacific Basin communications precludes the establishment of communications half links to each island by the global international carriers unless a prohibitive tariff is applied to the regionals users. These factors limit usage and access to world telecommunications and information resources by island residents.

The establishment of a Regional Network, however, would reduce these problems. Such a network would pool multiple types of communications traffic from a number of different islands and users, utilizing a variety of bandwidths and interfaces. It would interface as a transit carrier directly or indirectly with each of the international carriers providing the island's individual and corporate users full access to world communications and information resources.

By pooling traffic of multiple types, to multiple destinations and carriers, and providing for intra-regional traffic, sufficient usage can be generated to allow most smaller populations to support a terminal site on this network. The cumulative traffic routed through a common gateway to the major carriers (without each one being required to provide dedicated half links) will be significant enough to justify favorable interconnection rates and policies for regional users. (7)

There are several methods by which an island government can participate in the services of such a network. The specific type of relationship that a given island nation would enter into with the Regional Network would depend upon local political and regulatory conditions. It is also possible that the relationship will change over time as the Network expands and increases its services. Whichever option is chosen, the pooling of Pacific Basin communication traffic will permit the development of an economy of scale for the governments and users of the region.

5. IMPLICATIONS OF THE REGIONAL NETWORK

The establishment of cost effective voice, data and video, communications within the Pacific Basin will have a major impact on Pacific island societies. Educationally, it will provide resources to remote island students who have been denied them in the past. Access to audio and video conferenceing and online services will greatly expand the horizons of students and teachers. These services will allow the development of effective distance education courses at all levels, greatly strengthening curriculum throughout the region.

Economically and socially, the Network will provide a variety of benefits. Among these will be such things as: long distance telephone; tele and video conferenceing systems; electronic mail; electronic fund transfers; credit card verification; online purchasing of a variety of different commodities; credit referencing; airline and hotel reservation services both within and without the region; medical consulting services; access to world data bases and online journals for government and business and academic researchers; better and speedier communication between island governments, etc. (9)

It should be noted, that the establishment of effective communication and information systems in the Pacific cannot help but change island cultures and societies. As new and better methods become available to island residents, and as islanders come in contact with different cultures and value systems, the societies and cultures will change.

This change will be especially significant within the areas of education and access to information. On the one hand the development of effective distance education programs and local access to the world information system may lessen the negative effects of modernization. Families and the local economies may suffer less disruption because of individuals removed from them to secure an adequate education. Sharing information and knowledge between islands and with the rest of the world should aid in problem solving, cultural preservation, and mitigating the negative social, economic and political ills associated with development.

On the other hand, Pacific island cultures have traditionally viewed knowledge, information, and skills as the private possessions of individual clans/lineages. To a certain extent traditional systems of authority and status have been based upon and reinforced by their elites ability to limit access to information and education within their social systems. Similarly, the cultural and linguistic integrity of the Pacific Basin has depended upon the region's remoteness, isolation and its inability to easily communicate with the rest of the world. Open and easy access to information and communications by the general population may necessitate a revision and change in traditional authority and status relationships.

6. CONCLUSION

The creation of a Regional Network which provides increased access to information and modern educational programs to islanders, who have not had access to these systems in the past, will change the region's political, social, economic and cultural systems. While the precise nature of these changes remains to be seen, it is becoming increasingly clear that some realignment in authority relationships might take place and that regions cultures and languages will come under increased pressure for change within the next decade. To minimize the negative aspects of these changes, regional governments and the Regional Network will have to work together to develop controls that will allow change to take place without rending the Basin's traditional social and cultural fabric beyond repair.

Two Communications for Global Harmony and Linkage

Masao Yukawa
Mitsubishi Corporation
Tokyo, Japan

ABSTRACT

The deregulation of the Japanese telecommunication market, and the initiation of a competitive framework, took place in a very short time without the MPT having complete information or understanding of the market. Not surprisingly Japanese telecommunication companies are fighting to overcome a number of obstacles, specifically regulatory problems concerning monopoly status and information disclosure requirements, as well as technology issues.
A global shift from an economy of scale to an economy of coverage, to an economy of networks is occurring. Network businesses integrate both an economy of scale and an economy of coverage. The networks must be global, efficient and transparent.
How do I forecast the future?

Introduction

Today's world is growing smaller and smaller. Borders are breaking down, people are communicating by way of various telecommunication tools, such as telephone, electronic mail, facsimile, video conference through satellite and optical fiber links,and geographical differences are almost nil due to the advancements made in the field of information technology. A global society is being developed through various means, but because I sincerely believe that in order to build a truly global society, two types of communication are essential, namely, cross-cultural communication and information technology communication. Cross-cultural communication is the type of open-mindedness and communication that allows peoples from different cultures to understand the meaning of the messages they are sending to one another. And information technology communication is the means by which people all over the globe can communicate more timely and effectively.

Today I would like to talk to you about the revolutionary telecommunications industry, its impact on our global society, its development in Japan. and what I believe are the future trends of this dynamic industry.

I. New Classifications of Industry

In the traditional classifications of industry introduced some fifty years ago by Professor Clark, there were three types: the primary industry for agriculture and mining, the secondary industry for manufacturing and the tertiary for the services industry. Because of technological improvements and economic advancement leading to high and sophisticated consumer demand, I believe that the old classifications are no longer feasible; they relate to the supplier or producer class of industry, while present day economy is more related to the consumer. Thus, in order to better define our economic world, the classes of 1st, 2nd, and 3rd, will be replaced by the 4th, 5th and 6th industry classifications as described below:

The fourth industry is the information industry, which encompasses the use of information and information technology to manage relations between people (ningen), spatial relations (kukan), and time relations (jikan). In other words, information technology is the bridge between persons, space and time. The information industry supplies information data which might simply be called content as well as the means of transmission and process of the content, namely, hardware, software and service.

The fifth industry is the lifestyle industry, or "high touch", including the satisfaction, discipline and autonomy of human beings, particularly in the fields of housing, fashion, dining, health, culture, entertainment and leisure, including sports. Nowadays, it is "trendy" to be time rich, having enough time to enjoy life; health rich, in good health; mobility rich, with enough time and money to travel; and design rich, with money and fashion sense.

The sixth industry is what I call the spiritual industry, or religious industry, in the narrow sense of the word. This means ethics, morality and the meaning of life. These can be provided by traditional religious groups or by other groups committed to the achievement of human or personal potential. To realize this classification change from 1, 2, 3, to 4, 5, 6 are the fundamental requirement needed to understand our global society today.

II. The Impact of the Telecommunication Industry

It is the telecommunication that bridges between people, place and time. In the past, communication was made only face to face, and transportation was only used for moving goods and criminals or slaves. Now, any person, with the use of information technology, can communicate with anyone, anywhere and anytime. They don't need to move from place to place to communicate. Today, information technology can replace transportation for better communication. In order to create harmony and linkage, telecommunication is the essential tool.

Because of the rapid innovation of information technology, the borders that have been built over centuries are beginning to disappear. I like to think of telecommunications as a "block buster" of these borders, boundaries and barriers including those of:

1. Nations - with telephone, facsimiles, electronic mail and satellite broadcasting, people in one part of the world are able to communicate economically and timely. For

example, during the recent Gulf War, people all over the world could see the missiles flying on TV in real time. Moreover, the East European revolution would not have been known to the outside world without the use of telecommunications and the recent coup in the Soviet Union might have succeeded if telecommunications technology did not exist.
2. Industries - boundaries have dissolved and it is difficult to distinguish the boundaries of one industry from another based on the "merging" of different industries through advancements in information technology. For example, telecommunication and broadcasting boundaries have disappeared to create teleommunication-broadcasting, banking and securities businesses are difficult to distinguish. Through information technology, new services have been made possible, for example, in the transportation industry a worldwide quick delivery service become daily necessities.
3. Companies - industry barriers have broken down to enable companies to diversify their businesses, like in the case of a Japanese steel maker with its move to the production of computers and semiconductors, a textile company moving into the area of optical fiber cables, an agricultural equipment manufacturer becoming a computer maker, and a chemical company becoming a floppy disk and software maker.

We can see the heavy impact that information technology has made on business in general as well. Businesses can't survive, cannot provide solutions without information technology. No longer can businesses just provide products, they must provide solutions for the growing consumer demand for solutions to their needs and problems. For example, delivery companies rely on computerized data for scheduling, locations, etc. Banking and securities companies need computerized data for timely information to make accurate decisions. Point of Sales information is used by merchandisers to make planning and marketing decisions. And airline and other ticket entertainment businesses could not survive without computer data processing and transmission technology at their staff's fingertips.

These trends in breaking down the barriers will increase more and more through the improvement of information technology and with the deregulation of the industry. Without the national borders, industrial boundaries and business barriers, governments will no longer be able to define industries.

III. The Japan Experience

As you all know, Japan is one of the leaders in developing the information industry and is an essential part of the triad strategy of the development of many global communications businesses. The development of the industry has resulted in a very competitive marketplace and it is the Japanese experience which could provide direction and solutions for other nations who are not using the full benefits of information technology and who still maintain government-controlled monopolies in the telecommunications industry.

The two major reasons for this rapid development in Japan are deregulation and privatization. In 1982, the Second Adhoc Commission on Administrative Reform recommended that Nippon Telephone and Telegraph (NTT), be privatized and required to compete with Specialized Common Carriers. The main objective of this recommendation was to create a more effective communications infrastructure rather than to break up a monopoly. As a result the deregulation, competition in the telecommunication marketplace was introduced and partial restructuring occurred. The Telecommunication Business Law and the NTT Corporation Law went into effect on April 1, 1985, breaking up NTT -- with two requirements: one, that the Telecommunication Business law be reviewed within three years and two, that the NTT Corporation Law be reviewed within five years.

With this restructuring, telecommunication service providers were divided into two categories:
1. Type I - Telecommunication carriers possessing their own circuit facilities, and
2. Type II - Telecommunications carriers that lease the circuit facilities of Type I carriers.

With the deregulation that accompanied the privatization of NTT, a variety of different New Common Carriers (NCCs) were born. Competitors began rushing into the market in 1985, and in 1987, partial service was provided by these New Common Carriers. Today, the number of NCCs in Type I totals 66. In addition to NTT (and KDD - Kokusai Denshin Denwa, the international carrier), the number of carriers in each type of service is as follows:

Long distance	- 3
Satellite	- 2
Regional	- 7
International	- 2
Mobile	-16
Paging	-36

The major players in this category are varied. They include electronic and telecommunications equipment manufacturers, information providers, sogo shosha, financial institutions, securities firms, insurance companies, steel manufacturers, automobile manufacturers, construction companies, retail companies, transportation companies, publishing companies and broadcasting companies. These companies are participating as equity investors (aiming at a profitable return on investment from a successful venture), end users and as equipment suppliers.

In particular, the most aggressive companies to enter the rapidly growing telecommunications market are the sogo shosha. We, Mitsubishi Corporation are actively involved in the industry for two reasons:

First, we foresee that "sleepless" global networks will soon function as the "headquarters" of a business. While decision-making will become more and more decentralized in a worldwide organization, it will be crucial for the information to be centralized through both a "hardware" network - satellites, cabling, computers, and peripherals -- and a "software" network - information, ideas and people -- that have developed in organizations.

Secondly, in the present world, supply capability exceeds demand in almost every industry. Mitsubishi Corporation is handling some 30,000 products and services directly to its 30,000 corporate customers every year on a global basis. But, probably 90% of the products and services (supply capability) exceeds demand. Under these circumstances, we have to change from a product business to a solution business, which means that instead of selling products, we must sell solutions and we are constantly striving to be an excellent provider of the most

appropriate solutions for our customers. As a solution provider, Mitsubishi Corporation possesses two types of tools, or networks that are required:
1. infrastructure network: the basic information network on which the following network is based and operates:
2. info-structure network, including the people or human network - the creative/idea information network - the meaningful information network.

Because of these two reasons, Mitsubishi became a founder member of most of the NCCS, namely, DDI, Teleway Japan and Telecom Japan (domestic long distance carriers), TT Net and Osaka Mediaport (regional carriers), Space Communications Corporation (a satellite telecommunication company) and ITJ (an international carrier). As I was deeply involved in the founding of DDI, I am very pleased to say that among the NCCs, DDI was ranked No. 1 in 1990, with operating revenues of ¥155 billion and a net income of ¥11 billion.

Unexpectedly, most of the long distance, mobile and paging NCCs are enjoying good business results and are taking a relatively high share of NTT's market through their competitive strategies and more efficient operations. In some business areas, the NCCs have obtained over a 30% share of the market. This competition also generates more efficient and higher flow of information at cheaper prices -- resulting in remarkable growth of the Japanese economy and more competitive Japanese participation in the global telecommunication arena.

The Type II carriers, numbering 946 in early 1991, provide on-line data distribution and conversion, public database access, voice mail and leased circuit resale. Though this market in 1990 was estimated to be worth US $600 million, it remains unprofitable for all but a few operators. With this keen competition, there are still few leaders to choose from in the marketplace.

IV. Future Trends in the Telecommunication Industry

Since its beginning, the telecommunication service has been monopolized by one supplier. But now that the telecommunication has become a base infrastructure for every industry, the telecommnication serveices and products must move away from supplier-oriented to end-user or customer-oriented.

The technology of the telecommunication industry is changing rapidly, and in the coming decades we will see the speed of the development increase even more. Networking, open systems, downsizing (smaller and cheaper), and human interface/user-friendly products and services will be the rage.

Moreover, these changes will result in severe competition and more deregulation will be needed. The regulatory environment will indeed be challenged to cope with the changes I described earlier.

V. Conclusion

These trends are exciting for those of us in the telecommunications industry, but for the future development of the industry, it is essential that the information network must be global, more transparent and more efficient.
1. Global - it must be able to reach throughout the world, to tie people together so that they can communicate anytime, anyplace and with any person.
2. Transparent- so that all users can clearly understand the products and services available. This transparency is crucial and it requires a standardization of the protocol and systems that we have not yet seen in its entirety. Without standardization, interconnectivity and true communication is impossible.
3. Efficient - using the least amount of a person's most precious resource - time.

In order to reach these goals, I believe that separation of networks is not appropriate. Instead of separation integration of networks is crucial. For example, NTT, a domestic carrier should be allowed to conduct international communication business as well as KDD and vice versa.

Information technology is needed for the development of economies, to help create a better lifestyle for all peoples and to create global harmony and linkage. It is necessary for all of us to provide opportunities for the training of people around the world, and we must provide technological as well as financial support. This assistance will help other nations to develop their infrastructures and info-structures, resulting in a better lifestyle for our global society.

Today I have shared with you some of my thoughts on and experience in our revolutionary telecommunications industry. I look forward to discussing these in more detail with you during this conference.

Thank you.

THE PRODUCTIVE CONTEXT IN SOUTH KOREA: A HISTORICAL ANALYSIS

Deanna Campbell Robinson, University of Oregon, Eugene, OR, USA
Won Woo-hyun, Korea University, Seoul, Korea
Yoon Sun-hee, University of Oregon, Eugene, OR, USA

1. ABSTRACT

For the first time in the Republic of Korea's short history, the country's visual entertainment and information industries have the chance to become legally and economically stable. Their success depends upon crucial decisions currently being made by the government about future telecommunication infrastructure, ownership and system access. Government policies will determine whether the production industries are able to create an international demand for endogenous entertainment and information products as well as sustain a domestic market for them.

2. INTRODUCTION

In this paper we examine South Korean (Republic of Korea, ROK, Korea) telecommunication production opportunities (entertainment, news, information services) within the structural boundaries of 20th Century Korean society. We begin our analysis with a look at the historical evolution of film, telephone and television infrastructure and law. Discussion of the current direction of infrastructure and law then leads to an evaluation of production needs and capacity within the ROK. This assessment is tied to some closing remarks about South Korea as a potential cultural competitor in the international marketplace.

3. INFRASTRUCTURE HISTORY

3.1 FILM

Even though Korea was closed to foreigners and known as the "Hermit Kingdom" during the late 1800s, film came to the peninsula at about the same time it began appearing in Europe and North America. A French (Pathe) film may have been shown in Korea as early as 1898 and a short French film is known to have been screened in 1903. Seoul's earliest theaters exhibited American and French films even after the Japanese invasion of the peninsula following the Sino-Japanese war. This cultural freedom was short-lived, however, when Japan annexed Korea in 1910. Even though theaters spread rapidly around the peninsula, they were owned by Japanese and showed mostly Japanese films.

The first Korean film was made in 1919, the first feature film in 1923. The first motion picture company (Japanese) was established in 1924 and the first Korean company was founded in 1926. As many as 80 films per year by around 40 companies may have been produced in the late 1920s. Only about 10 films per year seem to have been Korean and that number dwindled throughout the occupation years to one or two. Korea's first sound features appeared in 1935.

Perhaps because some early Korean-made films were critical of the Japanese occupation (for example, *Arirang*), the occupational administration began censoring and otherwise restricting film production in the late 1920s. Many Korean filmmakers fled to Shanghai in the 1930s where they continued to make films, although these could not be viewed by the Korean public. The 10 remaining Korean film companies were closed by the 1940 Chosun Motion Picture Law and replaced by a single Japanese company (Chosun Film Company, Ltd.). Even stricter censorship and occupational circumstances led to production of mostly propagandistic films.

After World War Two, the peninsula was divided into North and South Korea with the latter under the temporary administration of the U.S. Military Government in South Korea (USMGSK). Despite the return of exiled filmmakers and the screening of previously-censored films, the revitalized South Korean film industry remained constrained by military restrictions. The USMGSK was anxious to defuse any leftist sympathizers in the southern peninsula and cracked down on leftist media of all kinds. It also asked the Chosun Film Construction Headquarters (born in 1945) to make newsreels.

The southern half of the peninsula became the Republic of Korea in 1948 with Rhee Syng-man as its first president. The use of film to further government purposes intensified during the Korean war in the early 1950s but film facilities and financial resources were wiped out. For several years after the cease-fire only a few 16mm films were made, most of which rehashed the war and its consequences.

Out of the circumstances of poverty and an agrarian economy a system of film financing called "iptosonmae" was born. Just as poor farmers began pre-selling

their crops in order to cover their expenses, film financiers set up a system to collect equal shares from promoters and theater owners in five regional blocks outside Seoul, a system that still exists. Promissory notes from these sources enable filmmakers to borrow enough money at high interest rates to cover the exact projected costs of producing a specific film.

Despite the adverse circumstances necessitating this unsatisfactory but imaginative financial scheme, film remained an important element of Korean culture. By the late 1950s theaters were rebuilt, the first colored films appeared and South Korea began to participate in international film festivals. Filmmakers gained a one-year respite from heavy government censorship between the forced resignation of Rhee Syng-man and a military coup by General Park Chung-hee (1961). Park's assumption of power brought severe curtailment of freedom of expression.

Under Park, film production soared (an all time record number of Korean films, 230, were made in 1969) but at the expense of source diversity. A series of Motion Picture Laws (MPLs) bankrupted many of the 71 production companies by requiring them to make at least 15 films per year, permitting those who met this quota to import foreign films. This arrangement led to the partial use of import profits for subsidization of domestic Korean production, a practice that persisted until 1985. Foreign import quotas also were instituted along with the mandate that theaters screen Korean-made films on at least one-third of viewing days.

Even though these policies ostensibly were designed to favor local production, they resulted in the demise of many small companies. Heavy government censorship and the requirement that filmmaking be a profitable enterprise additionally encouraged "quick and dirty," highly commercialized production. Over two hundred films were made in 1970 but most of them were of very low quality.

Only three film companies existed in 1973, a situation unremedied by the Fourth MPL which again demanded production of a specific number of films per year, further limited imports, reimposed foreign screening quotas, controlled the supply of film and once more restructured the industry. Under this legal revision import and foreign screening restrictions were accompanied by some seemingly positive encouragements to indigenous film production. Companies that made "high quality" films were permitted to import more foreign films, a reward rife with possibilities for corruption because of the subjectivity involved in deciding what constitutes high quality.

The Park government also replaced the old industry association with the Motion Picture Promotion Corporation. The MPPC's mission to encourage the existing industry provided further opportunity for favoritism toward particular companies and filmmakers. Implementation of the Fourth MPL occurred just after passage of the infamous Yushin Constitution which gave Park martial law control of the country and raised doubts about the motivation behind any media regulations.

3.2 TELEPHONE

The basic law covering use of the electromagnetic spectrum was passed in 1961 (The Radio Waves Regulation Act). This law gave the Ministry of Communication (MOC) authority over all electronic transmission infrastructure. Because broadcasting construction was primarily financed by large, private companies and was less costly than the building of a universally-accessible public switched network (PSN), 25 times as many South Koreans had TV sets in 1979 (almost 6 million out of a population of around 42 million) as had telephones.

The Chun government reversed this pace of development. The ROK used foreign loans and customer deposits to finance construction of a PSN beginning in 1982 when the government-created Korea Telecommunications Authority became operational (KTA). At the same time the Data Communications Corporation of Korea (DACOM) was established "to accelerate the development of data communications and to rapidly build a modern information-oriented society" (KOIS, 1987). In 1983 the Basic Telecommunication and Public Telecommunications Business Acts became effective. The MOC continues to regulate all telecommunication infrastructure and delegates responsibility for public facilities to KTA, an arrangement that has increasingly important implications for endogenous entertainment and information production.

In 1990 KTA supplied about 37 telephones per 100 population. DACOM-NET served close to 5500 subscribers and DACOM provided leased-line service to over 80,000 parties.

3.3 TELEVISION

The American military government created the Korean Broadcasting System (KBS) from the previously Japanese-controlled radio network. The Korean military initiated an alternate service

in 1950; the U.S. military service added a station in 1954. The first ROK private station, a Christian service, also was born in 1954. Other private broadcasting companies--Munhwa (MBC), Dong-A (DBS) and Tongyang (TBC)--evolved from 1959 through the 1960s when most also began constructing television stations. South Korea's first TV station, established in 1956, was destroyed by fire in 1959. KBS, TBC and MBC set up TV stations from 1961 on.

The advent of television affected the film industry even more than politics and economic downturns. Government policies, low quality films and a population tired by twelve-hour working days aided the takeover process during the 1970s and early 1980s. TV ownership shot up from 880 thousand in 1970 to around 8.5 million in 1984. Conversely, the film audience decreased from some 173 million in 1969 to around 48 million in 1985; per-capita film attendance descended from a high of 5.7 in the 60s to 1.1 in 1986. Film exports decreased from 201 in 1971 to 6 in 1984.

Despite the enormous popularity of the medium, television infrastructure development did not fare well under Chun. In a general clamp-down on the media, the government restructured broadcast facilities. KBS absorbed all private broadcasting companies with the exception of CBS (the Christian Broadcasting System) and AFKN (the American Forces Korea Network) and the partial exception of MBC (70% of whose stocks were given to KBS, the rest to a private foundation). CBS was forbidden from carrying news, general programming and ads. The Newspaper and New Agency Registration, the Press Ethics Commission and the Broadcasting Laws were replaced with a single Basic Press Law which permitted tight government control over both print and electronic media. The Ministry of Culture and Information was given authority over content. This Ministry is now split into the Ministry of Culture and the Ministry of Information. The latter (MOI) now assumes responsibility for content regulation.

Chun's restructuring of the television industry not only affected freedom of expression within the country but it also relegated virtually all domestic television production to KBS and MBC. Thus, a financially viable independent video production industry was not feasible until Roh Tae-woo was elected president, the media laws were changed, and KBS and MBC began to be challenged by alternative methods of television distribution.

4. CURRENT INFRASTRUCTURE AND LAWS

Under Park's authoritarian rule the ROK transformed itself from a war-devastated infant nation to a newly-industrialized, internationally-competitive country. Under Chun, the ROK moved into high technology, especially communication technology, and began to compete with the more developed countries in their rush toward information economies.

Under Roh more liberal media laws and conditions have provided an ambiguous direction for further construction of communication infrastructure and possibilities for expanded cultural production. Although new electronic distribution outlets are proliferating and the administration is somewhat encouraging software production, the Roh government still tries to control content, only more covertly than the Park and Chun regimes.

4.1 FILM UNDER ROH

The Fifth MPL (effective 1985) ruled that film importing and production houses could still be owned in common but that their operations had to be strictly separated. Importing companies now are required only to register rather than to acquire licenses. Intensified U.S. trade pressure resulted in the Sixth MPL (effective 1987) which gave foreign distribution companies the right to operate directly in South Korea. Foreign production companies also can establish operations in the ROK. The only remaining law protecting Korean filmmakers and producers is that theaters must still show Korean films at least two-fifths of viewing days.

Over 200 (as opposed to the old 25) foreign films are now imported into the ROK annually. In 1980 about half the audience share was realized by foreign films as opposed to 67% in 1986 and 73% after passage of the Fifth and Sixth MPLs. Regulatory changes have led to a staggering increase in the number of imported films (264 in 1989, 91 from the U.S. and 89 from Hong Kong).

Loss of audience is not the only consequence of market liberalization. The Seoul presence of large foreign distributors like UIP (Universal International Pictures) threatens not only the operations of domestic distributors but also the old structure of Korean film financing. UIP rather than Korean distributors will reap the profits from foreign screenings, thus removing the possibility for import subsidization of domestic production.

4.2 TELEVISION UNDER ROH

The existing government television system suffers not so much from lack of profits as from continuing control of

content. For example, Article 21 of the 1987 Constitution guarantees that "all citizens shall enjoy freedom of speech and the press." But Article 21 also says that "the standards of news service and broadcast facilities and matters necessary to ensure the functions of newspapers shall be determined by law." Article 21 further stipulates that "neither speech nor the press shall violate the honor or rights of other persons nor undermine public morals or social ethics" (ROK, 1987, p. 5). Thus, rights are accompanied by loopholes that provide the government with excuses for interference it thinks necessary.

The 1987 Broadcast Act, enacted one month after the Constitution, separates broadcasting from print media and cable systems. The Broadcast Act, although viewed as liberalization, strengthens loopholes available for control over radio and TV (e.g., see Articles 3, 4 and 5). Content guidelines contained in the Act provide formidable obstacles to scriptwriters and producers who want to get their material aired.

4.3 THE ADVENT OF CABLE TELEVISION

Even though the ROK had only small, mostly retransmitting CATV (community antenna television) systems in 1987, the legislature passed a Cable Broadcasting Management Act. This law, similarly to the Constitution and Broadcast Act, prohibits cable carriage of programs "which impede national security and public order; which disturb international friendships; which support or discourage certain interests, belief systems of specific organizations; news, editorials and advertising programs [except those already on "must carry" government supported TV stations] and other programs prohibited by the presidential decree" (Article 17, trans. Yoon Sun-hee). Article 15 of the 1987 Presidential Decree of the Cable Broadcasting Management Act further details content restrictions.

The law does not clearly spell out exactly how these regulations will be enforced or how cable content will be monitored. Nor does the law provide for import quotas, domestic production screening quotas or other protective measures. Legally, cable appears wide open to foreign programming as long as none of the content restrictions are violated by such material.

The country now has an estimated 900 CATV operations that serve around 3 million subscribers and one experimental cable system (which carries original programming in addition to retransmitting over-the-air signals). Many of the CATV systems, especially in the south of the country, are being challenged by Japanese DBS transmissions. But CATV systems only provide clearer representations of existing broadcast signals; cable systems will bring new programming and information services, some of which will be interactive. Consequently, communication experts expect cable to serve about 40% of households by the year 2000.

5. CURRENT PRODUCTION

As the Korean people increased their education and skill levels, they became more self-confident and less acquiescent. They insisted upon greater political freedom as well as higher wages and better working conditions, a campaign that continues today.

Until recently, South Koreans have had little time and money to spend on leisure activities. Those circumstances are changing rapidly. By 1991 the nation's 43 million people had attained a per capita income of US$5500, a figure that is expected to double by the turn of the century. Per capita leisure spending is expected to reach close to $1900 by the year 2000, an important development for endogenous cultural producers.

The largest problems remaining for cultural producers are how to raise capital, how to distribute their products, and how to find profitable niches in the international entertainment/information marketplace. The capital problem is exacerbated by an antiquated financial system used by the government to route people's savings to favored industries. So far, cultural production, including computer software, has not been given high government priority, although that situation seems to be changing as the biggest companies (chaebol) become increasingly interested in this economic sector.

5.1 FILM PRODUCTION

Because it is very difficult to recover high expenses from the small domestic market, Korean films cost only an average of 300-400 million won (approximately $400-550 thousand dollars) each (Kim, 1989a). Huh (1989) notes that only about one-tenth of the Korean films produced annually make a reasonable profit. In contrast an American film may cost over $45 million but has the opportunity to recover expenses and profit from a huge domestic and an immense international market.

Various estimates posit the existence of between 20 and 50 commercial film companies (mostly a single filmmaker). Most film companies are not financially stable and remain essentially one-filmmaker outfits. About 150 film

directors were registered as of 1989, only 60 of whom were actually producing films. Most film directors cannot support themselves and their families from filmmaking activities.

The iptosonmae system of film financing no longer works well for several reasons. The current condition of the domestic industry makes film investment risky so that regional promoters are not so willing to put their cash on the line in advance of production, especially for lesser-known filmmakers. Banks have never extended loans without considerable collateral. The increase in demand for endogenous productions should encourage investment in the industry.

In addition, promissory notes usually are issued for only 3-5 month periods during which films are expected to be completed, a practice that encourages poor quality aside from the amount of production investment. The MPPC is helping to remedy these problems but the amount of money it has for this purpose is still far from adequate despite increasing government funding. In 1986 the revitalized MPPC established a "Selection Committee" to choose high quality films and offer their makers one of two forms of support: funds for advertising the selected films or for production of subsequent films.

The MPPC received a 1989 government grant of 2.5 billion won ($3.5 million) to subsidize film activities (4 billion in 1990 and 5 billion in 1991). The same year it also acquired 4 billion won ($5.5 million) from box office receipts under a plan whereby theater owners pay a percentage of ticket receipts to the Culture and Arts Promotion Fund which promotes cultural activities around the country.

Interest-free production loans also are financed by money collected when film companies register with the government. Producers deposit 50 million won with the government and then receive nine-tenths back to produce the film. The other one-tenth supports overall film production. The MPPC also helps screenwriters, makes screenplays available to filmmakers and trains filmmakers. It is spending about one billion won ($1.4 million) each year on expanded and upgraded production facilities and equipment. In 1989 MPPC President Kim Dong-ho described plans for a new state-of-the art Hollywood-style production center to be completed in the next few years (1989, p. 46).

Production houses are encouraged to make higher quality films by increased support from the MPPC as well as the legal need to no longer depend upon import profits. Consequently, the ROK made 111 feature films in 1989 and exported 23. A number of these films were rewarded for their quality. Since 1987 Korean films, actors and actresses have won prizes at the Swiss Locarno Film Festival, the Moscow International Film Festival, the Venice International Film Festival and the Montreal Film Festival among others. The ROK also has set up a number of film awards: for example, the prestigious "Grand Bell Prize," the *Hanguk Ilbo* best film award and the Korean Association of Film Critics prizes. Undoubtedly, scriptwriters and directors have been helped also by the replacement of government film screening with industry self-regulation. One less positive side effect of this change is the increased production of soft porn films.

5.2 VIDEO AND INFORMATION PRODUCTION

At the end of 1990 South Korea had less than a dozen viable video production houses (capable of producing broadcast-quality TV). In expectation of a newly lucrative domestic software market, larger and more financially stable production companies are springing up.

Seoul Telecom, set up by the Dong Ah group in July 1988, is a prominent model for future production companies. It already contracts with ESPN and CNN and produces for MBC. Its goals are to be the top Korean as well as an internationally competitive production house. It is preparing to produce news programming with the expectation that the existing cable and broadcasting laws will be changed enough to permit multiple organizations to produce and distribute electronic news material within South Korea. Unlike most of the small broadcasting producers and commercial film companies, Seoul Telecom can afford to lose money until permanent cable networks and the new private television station are well under way (Chung, 1990).

Domestic software capabilities eventually will have to expand beyond film and video production. The country hopes to introduce wideband ISDN around the turn of the century; installation of a two-way cable system can be seen as an early stage in construction of a very broadband electronic highway into all South Korean homes and businesses (see Robinson, 1990). Domestically-originated value added services will require appropriate computer software.

6. DISTRIBUTION INFRASTRUCTURE

South Koreans now have about 1.2 TV sets per household, 80% of them color. 30% of those homes also have VCRs (about 3 million units). By 1995 VCR sales are

expected to hit 500 billion won (about $715 million). Reportedly, over 6 million of the 7 million prerecorded videos in South Korea are foreign made. The film industry has been slow in linking up with advanced technology industries.

The Korean government recently strengthened film and video production indirectly by creating more screening opportunities for domestic products. An experimental cable television system was launched in July 1991 and a new, private broadcasting station was expected to begin operation by the end of 1991.

6.1 CABLE (CATV) TELEVISION

The Electronics and Telecommunications Research Institute (ETRI) expects the cable TV industry to generate in excess of US$4 billion by the mid-1990s, almost $1 billion of which will come from the software market.

Responsibility for the experimental cable television system installed this year in two Seoul areas (8400 homes in Mokdong and Sanggyedong) has been assigned to three entities: infrastructure construction to the Korea Telecom (privatized and renamed KTA), system management to the Ministry of Communication (MOC), and programming (software) to the Ministry of Information (MOI). The system offers 7 channels during day hours when broadcasting stations do not operate (10 a.m. to 5 p.m.) Four channels retransmit existing over-the-air signals and 3 carry auxiliary programming and regional information. Two-way services include home security and fire protection. The government plans to construct 25 cable systems in 50 cities by 1993. Eventually each district's cable system will have 20-30 channels.

Critics have viewed the government's introduction of cable TV as a way to avoid deregulating government controlled broadcast TV. They also object to government control over cable. Currently, the MOC supervises transmission facilities and authorizes Korea Telecom (renamed because of privatization even though the government still owns the stocks) to construct all telecommunication infrastructure. The MOI licenses CATV managers and program producers and recommends people for Presidential appointments to the CATV Broadcasting Commission (charged with supervision of decency standards and cable administration). Dissenters have suggested alternative arrangements such as municipal or Commission licensing, free market supply of programming and an integrated legal structure achieved by combining the now separate cable, broadcasting and radio waves acts.

Another cable policy issue has been whether chaebol (Korea's very large conglomerates) should be involved in cable management. The government has decided to permit chaebol involvement; Korea's largest companies are preparing to participation in all aspects of cable hardware and software provision.

The government also is considering the case of press involvement. Press companies want to enter both the management and programming aspects of cable TV. The 1987 Cable Broadcasting Management Act forbids newscasts on CATV (the term used in the act) except those carried on KBS and MBC, whose channels cable companies must carry. The same reasoning applies to cable advertising under the 1987 law. This law obviously is outdated as it applies only to the old concept of CATV (community antenna television) as a retransmission system and misapplies to cable television as a program origination source (see Robinson, 1990).

6.2 PRIVATE BROADCAST TELEVISION

Introduction of the new private television station in Seoul, expected to offer one channel by the end of 1991, has been even more controversial than planning for cable television. Many media experts and broadcasting personnel regarded installation of this new station as a political move by the government to better ensure a favorable outcome in the ensuing presidential election. For several years before creation of the new station, KBS and MBC had been airing programs sympathetic to the complaints of workers and poor people, a practice critics say led the government to conclude that the two networks were being dominated by leftist, anti-ruling party interests.

According to these critics (predominantly university professors, KTA/MBC workers and the opposition party), the government created the new station in order to diffuse the effect of such programming on public opinion by splitting the viewing audience. The government maintains that it is trying to loosen up the media situation, encourage more diversity, move to a more privatized situation, and provide greater opportunity for broadcast advertisers. It also insists that it merely implemented recommendations contained in an electronic media study conducted by Korean media experts, the same people who later objected to the government's compliance with their suggestions.

Unfortunately, the juxtaposition of the act that created the new station with two other broadcasting system revisions passed by Parliament at the same time lends credence to critics'

arguments. The appointment of the KBS President was put under the executive branch and the Korean Broadcasting Commission had its policymaking function removed and the status and number of its commissioners reduced. These revisions were passed after members of the opposition party walked out of initial hearings.

The government also was accused of manipulating stock ownership so that it could retain control of the new broadcasting system which will be called the Seoul Broadcasting Company (SBC). The selection of Tae Young as the largest stock holder was fraught with intimations of corruption. For example, the company's stock prices jumped 72 percent just before its selection, its president has been closely connected with the ruling party, and the company has acquired various public construction contracts in the past. The president of the new private company, Yoon Sae-young, did not help matters when he declared that the station would target a middle class audience and reflect a conservative ideology.

Despite this controversy, the station should benefit the endogenous production industry. Unlike KBS and MBC (which produce more than 98 percent of their own programming), SBC has announced that it will rely completely on external production.

The government also is thinking of permitting some local broadcasting stations around the country and plans to launch a direct broadcasting satellite of its own in 1995. In addition it could lease an Asiasat transponder for both domestic and foreign future distribution of locally-produced programs.

6.3 OTHER INFORMATION INFRASTRUCTURE

Just as it pressured the ROK to open its film market, the U.S. has insisted that South Korea open its electronic information services market. The Telecommunications Business Act 1989 revision was designed to encourage telecommunications competition but did not specify exactly what kind of competition or how it could be introduced in specific information markets, problems that are now being worked out.

Questions remain about interconnections among private networks, access to international networks, and utilization of packet-switched networks. Restrictions in these areas kept the number of 1990 operating VAN providers to about 20, only 8 of which could provide data services to the general public. DACOM had been enjoying an unrestricted competitive edge. When competition was introduced, the company began offering cheaper, easier access and faster services with better back-up systems. The company also began to demand the right to own lines rather than being forced to lease them (at half price for long-distance) from the telephone company. Both companies moved toward utilization of packet networks for data transmission services.

The ROK debate is repeated in many other countries where interconnected private networks are favored not only by entities who build them but also by computer software companies who write operation and interconnection programs for them. Telephone companies, on the other hand, want to offer value added services universally on a centralized, monopolistic basis whereby both hardware and software can be easily standardized and all messages digitized and treated in essentially the same manner.

Strong private networks would encourage computer software production in the ROK but would decrease the infrastructure advantage offered by Korea Telecom control over telecommunication infrastructure. If multiple systems are constructed, a universally-accessible and economically-efficient integrated broadband network will be much harder to achieve, the situation now applicable in the U.S.

7. THE FUTURE

The Korean practice of using media income to support cultural production provides a potential means of ensuring the country's production future. Although the cultural support money raised from theater ticket sales is threatened by new film distribution laws, the Korean Broadcast Advertising Company (KOBACO) cultural fund can be increased by new opportunities for electronic advertising.

KOBACO now sells all television and radio advertising time on the two government controlled networks, KBS and MBC. It gives most of the revenue to the broadcasting companies but keeps a percentage for its own operating expenses, journalistic training, and development of the culture and advertising industries. Part or all of a similar electronic advertising fund and/or subscriber surcharge could be used to subsidize endogenous software production. Precedents set by existing and past practices make this a culturally and politically acceptable possibility.

Even if the endogenous production industry is strengthened by government (the government has been working on a 10-year culture development plan) and/or private subsidies, the fledgling

software industry will have to become export-oriented in order to make enough profit to guarantee its future financial stability. Kim Dong-ho, President of MPPC, commented in 1989 that Korean

> motion picture promotion policy in recent years . . . has been directed primarily toward cultivating the competitiveness of Korean cinema against foreign films, creating the environments conducive to the production of films with high artistic value, and acquiring the basis to explore the overseas markets for Korean films (1989, p. 45).

The MPPC and companies like Seoul Telecom already have established a national direction for internationally competitive production. The question remains as to exactly what kinds of Korean cultural products can be marketed internationally.

Huh (1989) suggests that American creativity and big production budgets successfully turn out highly entertaining films dependent on visual appeal and vivid representation of unusual occurrences. He believes that Korean filmmakers, because of their low budgets and lack of creative experience, should concentrate on making "serious films which address social problems or human experience" (p. 13). Korea's famous director Bae Chang-ho agrees with Huh's general goal for Korea's filmmakers:

> We Koreans today are in the throes of a heady and drastic process called modernization. Against the background of this kind of fast-changing society, so many people are presenting so many real-life comedies and tragedies almost daily. This, in other words, is a country so full of good stories for cinema. This is what makes the circumstances surrounding the motion picture industry in south [sic] Korea today so great (Bae, 1989, pp. 16-17).

Korea's cultural producers have always lived within unique circumstances. Their creative lives during most of the Twentieth Century have been shaped by political and economic events beyond their control yet they have managed to survive perhaps better than their more fortunate colleagues in many other countries. Now they are faced with a new era of relative personal freedom and a highly competitive and internationalized environment. Gilmore tells us that

> The talents and capabilities of [Korea's most accomplished] directors, as well as first-time filmmakers like Bae Yong-kyun, are indisputable. But they need the opportunities and the resources which will allow for aesthetic and cinematic decisions to be made outside of the context of the marketplace, and allow for the fulfillment of their inspirations (1989, p. 23).

Gilmore really argues for the needs of cultural producers the world over. He speaks to the contradictory circumstances under which artists and programmers work everywhere, the struggle between the liberty to make decisions outside the marketplace context and the economic freedom that comes with successful exploitation of that marketplace.

GETTING TO GRIPS WITH THE PRIVATISATION OF TELECOMMUNICATIONS IN MALAYSIA

Dr Syed Hussein Mohamad, Shanmugam Manickam & Rema Devi
Telekom Malaysia
Kuala Lumpur, Malaysia

1. ABSTRACT

This paper highlights the experiences of Telekom Malaysia as a privatised entity in a developing country. It concludes that while a mature market in terms of penetration is not mandatory for privatisation to be successful, a sound regulatory framework must be present to lend market certainty to potential investors. However, strong management is essential to make privatisation a commercial success.

2. Introduction

MALAYSIA has led the ASEAN region in moving its telecommunications entity from a Government monopoly to privatised enterprise. Rare in its boldness, it also marked the beginning of challenges, problems and solutions hitherto unknown to the Company.

The formulation of a national policy on privatisation has been central to the creation of Telekom Malaysia. First enumerated in 1983 as a policy aimed at emulating the spirit and track record of the private sector, privatisation has developed into a full-fledged policy accompanied with a well-defined Masterplan as well as an Action Plan.

Among the main objectives of the Government's privatisation policy was to reduce its presence in the economy. As important were the aims of increasing efficiency and productivity, reducing the Government's financial and administrative burden, and achieving equitability in the distribution of the nation's wealth.

3. Run-up To Privatisation

Preceeding Telekom Malaysia's privatisation was the process of "corporatisation", best described as a grooming process for privatisation. It is a process by which a Government department or agency is first placed on a private sector legal and commercial framework, but in which the Government remains the sole owner and shareholder, and management is in the hands of the Board of Directors.

Grooming has involved turning around the company and imbuing commericial practices so as to make the company better reflect its true worth. In the case of Telekom Malaysia, corporatisation commenced in 1987 with the issuing of a licence to the operating company and the creation of a regulatory unit within the Government, Jabatan Telekom Malaysia (JTM), both cloned from the previous government department (also named JTM).

The transfer of activities of a business nature from the Government entity to the new corporte entity involved numerous legislative changes resulting in the following:

- Telekom Malaysia assumed total management responsibility;
- Telekom Malaysia took over both the assets and liabilities of JTM;
- Telekom Malaysia took over all staff of JTM, who adopted the option of employment with the Company.

The highlight of the entire exercise was the end of the 4-year grooming period in November 1990, when Telekom Malaysia shares were listed on the Kuala Lumpur Stock Exchange (KLSE). The paid up capital was increased to 1.5 billion ordinary shares, and 470.5 million new ordinary shares were issued during this mammoth exercise. At the end of the day, Telekom Malaysia emerged as the largest public company to be ever listed on the KLSE, accounting for about 15 per cent of the total KLSE market capitalisation.

Today, the shares are still substantially held by the Government and approved isntitutions, while about 25 per cent is held by the general public, of which about one-third is held by foreigners.

4. Managing Inherited Problems And New Goals

Clearly, at the time of corporatisation, the Malaysian telecommunications market had not quite reached the maturity of that of developed nations. This posed peculiar challenges for the Company, as it had to prepare the financial basis for eventual listing while at the same time undertake substantial infrastructural development.

In response to the needs of the Company and the environment, various priorities were identified:

- First was to create an organisation which is both customer oriented and market driven.

- Secondly, a shift in corporate strategy was effected, emphasising marketing techniques for both traditional and new services rather than depending on natural market growth.

- Thirdly, quality of service was upgraded so as to encourage customer loyalty and greater use of services.

- Fourthly, sound financial management was implemented so as to be able to undertake network expansion, modernisation, computerisation, new services, and finance projects of socio-economic importance such as rural telecommunications, and yet achieving a good profit track record.

A decisive action plan was drawn up to meet the new, rather daunting challenges. These included:

- **Strengthening the organisation** through training of management staff in the business aspects of operations and investments, incorporating business planning, strategic thinking and proper management reporting. The organisation was also restructured in line with the rethink in corporate strategy, the main aim being to make the organisation more proactive and responsive to changing situations.

- **Increasing market penetration and take-up of services** through innovative sales ideas as well as fully utilising network capacity.

- **Introducing new services and businesses** so as to meet the varying needs of a burgeoning and discerning residential as well as business community.

- **Servicing the customer** through effective, automated billing, and prompt handling of customer complaints.

- **Optimising capital investments** by improving the mechanics of evaluating and approving capital investments. However, in instances where viability was not the primary criteria, efficient use of funds was emphasised.

- **Controlling operating expenditure** by reducing wastage and promoting the efficient and effective use of resources.

- **Improving inventory management** by strict supervision of new purchases as well as available stocks. A computerised inventory control system was defined and specified (and is presently operational), while a consultant was engaged for an overall appraisal of stores management.

- **Credit Control** by tightening procedures as well as improving billing and collection. As a result, the amount of trade debtors dropped to MR$362 million at end-1987 and has continued to drop thereafter.

- **Reducing interest payments and foreign exchange exposure** by prepaying foreign loans with cash surplusses made available through prudent operating and capital investment policies.

The various steps above were also necessitated by the fact that corporatisation meant that the Company no longer enjoyed the privileges and subsidies of a Government department. The increase in operating cost (eg vehicle licences and higher overtime) arising from the change of status was about MR$70 million in 1987, the first year of corporatisation.

5. Reaping The Benefits, 1987-90

As the first Government utility to be privatised, expectations ran high as to the revenue and market potential that the new company would unleash. However, the results of the first year of operations proved to be an eye-opener, and a case study of sorts for future privatised entities.

Against a meagre pretax profit of MR$4.9 million, expenses had jumped to a level almost equal to revenue. It was a case where with telephone growth of 8.5 per cent and mobile growth of 60 per cent, the telecommunications market was healthy but the Company was not.

It was concluded that the effective strategy that promised the kind of marked improvement needed to meet the 5 year flotation deadline, was aggressive growth in customers and sales, coupled with quality. The net effect of this strategy on the financial and business strength on the Company is outlined in the table below:

	1987	1988	1989	1990
Revenues (MR$mil)	1,644	1,882	2,141	2,574
Pre-tax Profits (MR$mil)	5	180	366	564
Return on total assets	0.1%	2.3%	4.8%	6.8%
Total telephones (mil)	1,131	1,247	1,388	1,585
Telephones/100 population	6.8	7.3	8.0	8.9
Mobile users*	17,400	27,300	39,400	54,600
Public payphones*	6,000	6,600	7,000	7,300

* does not include those of competing operators

As can be seen, both the financial performance and financial efficiency of the Company have shown admirable improvement, while the growth in profits of 115 times over 1987-90 has been acknowledged as exceptional. Market growth, which was initially affected by the economic slowdown in the mid-eighties, has been revitalised and set on the path of high growth. Registering 14.2 per cent growth last year, customer growth has been projected to grow at 15 per cent in 1991. As of June 1991, total telephones had reached 1.7 million (penetration of 9.2/100 population), and the number of mobile users reached 62,770.

6. Regulatory Issues

Regulation of the privatised telecommunications industry in Malaysia has been tailored along that of the UK, and is vested in the JTM. However, the forces unleashed by privatisation has made the need for an overall industry policy on both regulation and competition compelling. Fortunately, the matter is presently being addressed at the highest levels of decision-making in the country, and we hope for some resolutions soon.

What complicates regulation in the Malaysian case is that it has to do with an almost traumatic transition from a regulated monopoly to a multiplayer competitive playing field. Presently, the tendency appears to be to heavily regulate the existing national operator and at the same promote competition.

This has made regulation and regulatory decisions the most significant in terms of long-term impact on the Company. The Company handles this through consistent contribution at the various policy sessions held with the Government, while closely monitoring its impact at all times. The impact on some facets of the Company is stated below:

6.1 Services:

Telekom Malaysia operates under a licence to establish, maintain and work a telecommunications system providing domestic and international voice and other services to the public, for a 20-year (renewable) period. Under the licence. Telekom Malaysia must also

permit interconnection to its system from other operators, and levy uniform additional charges on these operators.

While the Company is assured of the business that was handled by the Government entity prior to corporatisation, this is nevertheless subject to part or parts of that business being transferred to others. At the same time, there is no assurance that in so far as new businesses are concerned, the Company will be allowed to enter them, despite being the first to request for authorisation.

The experience thus far seems to indicate that while the obligations expected of the Company (as enshrined in the licence) are explicit and expandable, the rights to its present business and access to new businesses are not guaranteed. Additionally, the scope of service has also been found to be open to amendment. It is for this reason that firm guidelines on regulation are crucial.

6.2 Price:

The pricing of basic services is currently provided for in both legislation and the licence, which states that rates for telecommunications services or for access to the network shall not increase by an annual percentage which exceeds the annual average increase in the consumer price index (CPI). There has been no change in the rates for rentals since 1983, nor for call charges since 1985, despite corporatisation.

Applications to establish or change rates are made to the Minister of Energy, Telecommunications and Posts, who gives final approval. This also applies to tariffs for new services, where there are no established criteria for charging.

In line with worldwide trends, the move towards cost-based pricing is in the pipeline, and the Company is getting ready by establishing an appropriate costing system. On the control side, it is not know what mode of price control the Government will adopt, but the Company is advocating the price cap based on a weighted basket of prices.

6.3 Quality of Service:

The development of quality standards has to a large extent been an internal company effort rather than one that is formalised. The licence, however, does require that a code of practice for consumer affairs be enforced; such a code has been drawn up and is made widely available through the telephone directory.

Internally, the Company has set its own targets for quality of service as well as for network quality. In terms of service, customer complaints is targetted to decrease from 0.7 complaints/DEL to 0.5 in 1995, while the restoration of telephone faults within 24 hours is targetted to improve from 94.3 per cent in 1991 to 96.5 per cent in 1995. Yet another criteria, operator response within 10 seconds (for all calls of all categories), is targetted to reach 100 per cent in 1995.

6.4 Social Obligations:

A unique and key feature of the regulatory framework drawn up in the Malaysian privatisation exercise is the mandatory nature of community service obligations. This is provided for not only in Telekom Malaysia's operating licence but also in the 1985 amendments to the Telecommunications Act 1950.

Specific provisions for promoting rural communications in Malaysia is a notable case in point. The Company has budgetted some MR$1.7 billion for the 1991-95 period for the provision of rural telecommunications, progress of which is monitored by a special committee on which the Government is represented. On average, Telekom Malaysia spends some 16 per cent of its capital expenditure on rural areas, which also account for some 13 per cent of subscribers.

The licence also provides for directory information and public emergency call services to be provided by Telekom Malaysia. Maritime emergency services and public call boxes are also social obligations the Company is expected to meet.

Telekom Malaysia has always been of the view that the burden of the rural obligation is a shared responsibility which other operators should also subsidise. It also felt that the universal service obligation should be made incumbent on all operators within the market segment that they are in.

6.5 Competition:

Competition in the local telecommunications industry presently exists in the areas of cellular mobile and public payphones. In the case of cellular mobile, Celcom competes with Telekom Malaysia's nationwide NMT 450 Mhz service with a predominantly urban E-TACS 900 Mhz service, while Uniphone provides payphone service in franchised urban areas. Telekom Malaysia is disallowed from competing in paging and radio trunking services, both highly competitive areas of business.

It is unclear what the official Government stand is on competition in the basic telephone service, but it is not expected to materialise in the near future. However, the Company is of the view that an official competition policy needs to be formulated, backed by a supporting institutional framework.

7. Points To Ponder

Not all privatisations are straightforward deals commencing with expressions of interest to buy a telco and its business, followed by hard negotiations and eventual sale of equity. To a large extent, the manner a country chooses to adopt depends on its needs and internal experiences. In this respect, we believe that the Malaysian experience raises some interesting questions for both developing as well as developed nations. For example:

7.1 What has privatisation facilitated that would have otherwise not been possible?

Freedom to chart the Company's course, mindful of national and consumer interests, but without being shackled and delayed by Government procedures comes foremost to mind. As an independent company, Telekom Malaysia has been free to manage its own finances, control human resources in a more strategic manner, reorganise the company to meet immediate corporate needs, chart career paths for its staff, as well as encourage a cross-disciplined approach to problem solving. Privatisation has also granted the Company the autonomy to make wider availability of service.

Human resources has been a particularly challenging area for the Company in the sudden transition from government to private. Nevertheless, the 60 per cent increase in telephone customers witnessed between 1987 and end-1990 has been achieved with the same number of employees, signifying a labour productivity improvement of 60 per cent over 4 years.

In the finance area, the Company has been able to innovatively prepay loans as well as arrange alternative financing schemes so as to reduce the debt burden. Proceeds from the flotation exercise in particular were chanelled to prepay loans.

7.2 Is a high penetration level necessary before privatisation?

We would argue that a high penetration is not a necessity, but that more importantly, the potential for a high rate of market growth must exist. In fact, it might even be said that a low penetration rate augurs better for the candidate to be privatised, in so far as it is a utility service provider.

It is our view that under natural market conditions, the penetration level will grow in tandem with economic conditions. A viable business, however, must be sustained through capable management.

Telekom Malaysia was fortunate that the above fundamentals were present and the Company was fairly healthy financially prior to corporatisation. Additionally, the nation's economic strength was also fairly strong.

7.3 What would be the sort of regulatory framework necessary for developing countries in a situation similar to Malaysia?

While theoretically regulation and privatisation can be said to be a contradiction in terms, it is our view that in any competitive situation, a referee must be present to police the various players, especially when there is a dependency relationship. Universal customer access brings with it the contentious subject of cost sharing, and the office of a regulator is essential for refereeing these issues. Licences merely serve to define the scope of business of each operator, but not the relationship between operators.

A developing nation, however, has unique characteristics that pose an additional challenge for the regulatory process. As has been stated, the community service obligation in respect of rural services is often contentious, especially when the privatised company must also prepare the financial basis for public listing.

Apart from balancing the profit motive and social obligations, a developing country may face the additional problem of having to manage high growth. For Telekom Malaysia, which is preparing for an annual customer growth of 15 per cent in the medium term, regulation should facilitate the achievement of high growth as well as social objectives.

Additionally, the object of the regulatory mechanism in a developing country must be specific. Clear guidelines in the area of service, price, quality of service, social obligations as well as competition is essential so as to inject certainty into the market.

7.4 Is the Malaysia privatisation experience ideal for the developing world?

Privatisation is by no means the panacea for the telecommunications problems of the developing world but it would be a good option to consider. This is especially so for countries seeking the benefits of independent funding, technology choice, service provision as well as organisational reform.

Much however depends on the political will to make the process a success, as well as the urgency seen for service improvement in the country. While the environment, such as the economic situation, helps ensure success, a country need not be at the height of economic success to reap the benefits of privatisation.

8. Future Prospects

Malaysia has a national vision and aspiration to be a fully developed nation by the year 2020. Spurring this Vision 2020 is the fact that the economy is presently one of the fastest growing in the world, having registered four years of consecutive growth with GNP averaging an annual growth of 13 per cent between 1987-90. Structurally too the economy has changed, with the main contributors to GDP being manufactured goods and petroleum rather than agriculture as in the years before.

Telecommunications has a key role in achieving this Vision, while satisfying the infrastructural needs of foreign investors flowing into the country. The Company's goal is to lift telecommunications in the country to a level comparable to that of developed countries by the year 2005. The number of telephone customers targetted for the year 2000 is 6 million, or one telephone for every 5 persons. All services will by then be provided through a modern and totally digitalised network.

On the agenda as a public listed company are possible listings on foreign bourses in the near future, which has tremendous implications for the Malaysian privatisation policy. It also makes credit control all the more crucial in meeting the expectations of investors as regards earnings and yield.

9. Conclusion

Telekom Malaysia has been fortunate that privatisation has worked well to achieve both national and corporate targets. The question for the future, however, appears to be how to achieve similar results in a multi-operator, competitive situation. Related questions would be how such competition should avert duplication of resources as well as sustain the core business.

There is today sufficient experience in privatisation around the world in privatisation to assist a country establish the rules of regulation and competition first, before adopting privatisation. We feel that an approach which views both privatisation and regulation as a single package is the most favourable, before the process itself is put into motion.

The industry regulator, the Director General of JTM concurs with this view. At a recent international seminar held in Kuala Lumpur, he has said: "I would...recommend to any country on the verge of privatisation to map out clearly the policies applicable in a privatised environment and the direction for the privatised company in order to avoid...differences in expectations."

DEVELOPING A SATELLITE COMMUNICATIONS POLICY FOR THE PHILIPPINES

Director, Policy & Regulation
Teleconsult Ltd.

1.0 ABSTRACT

The Republic of the Philippines, with over 7,100 islands, is ideally suited to satellite communications technology. Domestic Satellite Philippines (DOMSAT) commenced service in 1979, but by the mid-1980's had fallen on hard times and has been unable to meet service demand. Therefore, beginning two years ago, the National Telecommunications Commission (NTC) began granting provisional authorities to new satellite carriers to enter the market. At this writing, four companies have been authorized, and others are pending. However, NTC's actions have been taken in a policy vacuum, with no overall guidance from government or vision of the future development of the satellite industry in the Philippines. It is mandated that the market will be competitive and private-sector driven, but the rest of the picture is unclear, and policy issues are arising that need government attention.

This paper describes the background to the policy making process being undertaken by the Department of Transportation and Communications (DOTC). The state of the telecommunications industry in the Philippines is reviewed, and ongoing efforts to strengthen the role of the private sector analyzed. The innovative nature of the process is also discussed, since it differs from the traditional way in which policy has been developed in the past.

2.0 BACKGROUND

2.1 Government Responsibilities

The Department of Transportation and Communications (DOTC) is charged with the development of overall policy in the telecommunications sector. Such policies should promote the orderly development of the nation's telecommunications sector in a way which benefits the Filipino people and the economic development of the country. The National Telecommunications Commission (NTC) is the regulatory arm of the Department, and uses both the policy statements of the Department and the franchises granted by Congress as guidance in regulating the industry.

2.2 Broad Policy Framework

In 1990, the DOTC issued the National Telecommunications Development Plan (NTDP), which set out the Department's overall policies for the sector and established a comprehensive set of service-oriented targets through the year 2010. As noted by the DOTC Secretary in the Foreward to the document, it "takes an aggressive privatization stance", and affirms the Government's intention to establish an environment to "enable the private sector to confidently pursue the expansion and improvement of basic infrastructure and services that are efficient and that respond to market needs."

The policy for development set out in the NTDP is as follows:

"The importance of an efficient telecommunications network as a foundation for economic recovery and growth is well recognized, as is the critical need to accelerate the development of telecommunications infrastructure and facilities in the Philippines. Therefore, the Government's primary goal for the telecommunications sector is growth to the maximum extent warranted by demand and by resource constraints, particularly foreign exchange availability.

The following fundamental policies will shape and drive this central principle of 'development first':

*a. **Private enterprise.** Private enterprise shall be the engine of sector growth, providing an efficient vehicle for development.*

b. Sector self-sufficiency. The sector shall be financially self-supporting with intra-sectoral cross subsidies fuelling development and expansion toward universal access goals.

c. Network interconnection. All public telecommunications networks shall be entitled to interconnection with each other and interconnection with private networks will be encouraged. Interconnection agreements shall provide equitable remunerative arrangements that compensate for facility usage and that recognize the necessity for intra-sectoral cross subsidies."

The DOTC will use these broad objectives in setting policy and providing guidance for specific sectoral developments. In particular, these policies will be guideposts for the formulation of the Government's satellite communications policies.

2.3 Need for Governmental Action

The impetus for the DOTC, as the Government of the Philippines' primary telecommunications policymaker, to formulate a formal domestic satellite communications policy comes from many directions.

Generally, satellite communications offers great promise for bolstering the Philippine domestic telecommunications network. With more than 7,000 islands, many of them forested and mountainous, the typography of the country would seem to be ideally suited for satellite communications. In addition, the existing terrestrial network has only limited reach in many parts of the country.

The Philippines also has a very low telephone penetration level of about one per 100 population and many villages and municipalities have no telephones at all. To remedy the latter situation, the Government created the Municipal Telephone Projects Office (MTPO), a separate unit of the DOTC, following the passage of the Municipal Telephone Act of 1989.

The MTPO's objective is to establish at least one public calling office (PCO) providing basic voice and data capabilities in each of 1200 municipalities in the country -- 80 percent of the total -- that are not yet interconnected to the public switched network. Early analysis by the MTPO identified several locations where it wanted to place PCOs or rural exchanges as likely to be more efficiently served by satellite rather than terrestrial link.

The Philippines has not been completely without domestic satellite communications. Since the late 1970s, Domestic Satellite Philippines (DOMSAT) had been providing interconnection for domestic interexchange service through a network of 11 earth stations. However, during the late 1980s, the company fell into severe financial and legal difficulties that prevented it from expanding service, despite customer requests.

Against the backdrop of DOMSAT's drawn out difficulties, the National Telecommunications Commission (NTC) began licensing new satellite carriers about two years ago. However, from a policy standpoint, the NTC's actions -- while attempting to answer the question of what would happen if DOMSAT failed -- raised even more policy questions that needed to be addressed. (See fuller description in 3.0).

Finally, the explosion of satellite television offerings on the AsiaSat 1 and Palapa B satellites, and the beginnings of a cable television industry in the Philippines raised a host of new questions. These developments refocussed attention on TVRO licensing issues and questions concerning the unauthorized reception of international satellite television transmissions that had been pending before the NTC for some time.

3.0 INDUSTRY DEVELOPMENTS

3.1 New Market Entrants

At the time the NTDP was prepared, only one additional satellite carrier had been granted a provisional authority by the National Telecommunications Commission to begin constructing a satellite earth station network. Additional carriers have since been granted provisional authorities. The NTC's actions can be summarized as follows:

Liberty Broadcasting Network Inc.

The first to receive a provisional authority to begin constructing a network was Liberty Broadcasting Network Inc., a business radio services carrier. Liberty was granted a provisional authority on October 27, 1989, to provide service through an initial network of 300 "micro earth stations" working with one or more hub stations operated by Liberty. Proposed services include point-to-multipoint domestic and international data transmission, digitalized sound messages, store and forward facsimile services, and dedicated lease channel services at speeds of 1200 and 2400 baud.

Liberty was granted a provisional authority for a term of 18 months for domestic services only. The NTC, on September 17, 1990, issued a new order approving a change of equipment supplier from Equatorial to Satellite Technology Management, of the United States.

Liberty has reportedly been in discussions with Philippine Long Distance Telephone Co. (PLDT) about working together to establish a network of very small aperture terminals (VSATs). PLDT also has an application before the NTC to provide VSAT services itself. No action has been taken on that application yet. PLDT is the largest telephone carrier in the country, providing service to 94 percent of the nation's telephones.

Clavecilla Radio Systems Corporation

Clavecilla was granted provisional authority on September 11, 1990, to provide domestic services through a network of VSATs operating through a central hub station. The initial network would be designed to carry data, video and simultaneous voice data (SVD) services. Clavecilla was given 12 months to install its network and the provisional authority was given a term of 12 months.

Clavecilla was a family-owned record carrier founded at the end of World War II, which had devastated the nation's telecommunications network. The company had become an insignificant player in the domestic and international record market by the late 1980s. To prosecute the creation of its VSAT service network it joined with Global Mackay Cable & Radio (GMCR), one of the largest Philippine international record carriers. Later, a bill was introduced into Congress to permit the formal merger of these two companies.

International Communications Corporation (ICC)

ICC was given provisional authority on December 20, 1990 to construct an initial network of 200 small or VSAT earth stations. Proposed services were full duplex (two-way), point-to-point and point-to multipoint data communications. ICC was given 360 days to construct the network and to begin commercial operations, though the provisional authority was given a term of 18 months.

More recently it was announced that Australia's OTC International, a subsidiary of the Overseas Telecommunications Commission (Australia), had purchased 40 percent of the company and would invest $20 million in a joint venture to create a data, voice and video satellite network.

Capitol Wireless Inc. (CapWire)

The more recent entity to obtain provisional authority was CapWire, an international record carrier, on March 27, 1991. It was authorized to construct an initial satellite earth station network of 20 earth stations, primarily in the central and southern portions of the country. Proposed services included "toll quality" voice telephone communications and data communications links to other carriers. A hub station would be located in the Metro Manila area to facilitate interconnection with the national network. The provisional authority covered only domestic communications services, though authority to also provide international services had been requested.

In fact, however, CapWire, in between the filing of its initial application and the issuance of the provisional authority, had studies conducted and was actively pursuing plans for a much larger backbone satellite network. In October 1991, CapWire signed a memorandum of agreement creating a joint venture with the DOTC to own and operate 56 earth stations. These earth stations will be tied into an additional 30 stations wholly owned and operated by CapWire. This network will be used to provide carriers carrier services to other telecommunications operators as well as MTPO public calling offices and rural exchanges.

3.2 Recent Developments

At this writing, all of the new entrants have begun installing their systems, and it is expected that they will be providing service early in 1992, through several hundred earth stations scattered throughout the nation.

The assets of DOMSAT, having been foreclosed by the government's Asset Privatization Trust, have been put out to public tender, and five parties have expressed an interest in bidding on the system, including the monopoly international satellite carrier, Philcomsat.

4.0 POLICY ISSUES

4.1 General

The Philippines is perhaps unique in Asia for having a long established, private sector based competitive telecommunications market. Others, starting with Japan and now several more, are also beginning to introduce privatization and competition into the telecommunications sector. In the area of satellite communications, however, the Philippines has had a monopoly situation. Therefore, many of the policy issues being raised now regarding domestic satellite communications are of the sort that may be faced by neighbors in the region who are breaking longstanding PTT monopolies by permitting one or more satellite carriers to emerge.

Within the Philippine context, recent developments, such as the DOTC-CapWire agreement, have added an urgency to the policy formation process. Even before that agreement was signed, however, the regulatory actions taken by the NTC highlighted the need for a comprehensive policy statement by the Department concerning satellite communications.

4.2 Market Structure

The NTC's actions implied, but did not clarify the concept that two classes of satellite carrier would exist -- those offering retail, "VSAT" services, and those offering carriers carrier services. It is unclear whether this segmentation of the market is an appropriate or even practical long term approach. Telecommunications links to Manila, the nation's primary communications and commercial hub, are in short supply for both large users, such as extractive industries, government enterprises and banks with nationwide operations, as well as for domestic and international record and voice carriers.

It is unclear whether the terrestrial carriers who might opt for satellite links to Manila or elsewhere in the country should be required to chose among only CapWire and DOMSAT, the two carriers carriers, or whether they

should be permitted to seek the best combination of technology, availability and price from any of the satellite carriers.

4.3 Market Entry

In the NTDP, the Government stated that it would "discourage fragmentation of the Philippines market for domestic satellite service". At the same time, the benefits of competition have been well documented and are generally promoted by the government. The NTC's actions have created the potential for vibrant and useful competition in this sector. But, with five carriers now licensed to provide satellite service, the question becomes, what is the optimum number of satellite carriers now and in the future?

The objective, obviously, is to maintain an efficient and effective level of competitive tension in the market. But, as a developing country with a shortage of human and material capital and hard currency, the question becomes if and when additional players should be licensed for participation in the market. Further, the question takes on an added dimension based on assumptions about the market structure. A segmented market with two carriers in one service category and three in another is obviously different from a market with five carriers free to choose their product and service offerings to meet market expectations.

4.4 Ownership and Entrance Restrictions

The interests of certain related sectors, such as terrestrial telecommunications carriers, especially the dominant carrier, PLDT, and broadcasters, raises the question of whether certain parties should be restricted in the manner in which they may participate in the satellite communications sector or have an ownership interest in satellite carriers. Some broadcasters have already subscribed to capacity directly from Palapa to meet their own needs for nationwide distribution of television network signals. Beyond this, however, the question emerges as to whether broadcasters leasing space segment capacity should be permitted to provide services to others.

The Philippine Communications Satellite Corporation (PhilCOMSAT), the country's INTELSAT Signatory, has already expressed an interest in taking over DOMSAT. It might also someday become a purveyor of INTELSAT space segment capacity to domestic satellite carriers. The expertise it could bring to domestic satellite communications must be balanced, however, against its market power as the monopoly provider of international satellite communications services.

Finally, satellite communications, like all telecommunications, requires large amounts of capital. Local sources of such capital are limited. Currently, foreign ownership of communications companies is limited to by the constitution to 40 percent. Should a more permissive attitude towards foreign investment be taken?

4.5 Satellite Television Issues

The NTC has had a rulemaking process underway for some time addressing the issue of the licensing of television receive-only (TVRO) earth stations and the unauthorized reception of video signals being carried on INTELSAT satellites. However, larger issues loom, because of the growth in Asia of satellite video services specifically designed to attract regional audiences. While AsiaSat, with its package of television programming, covers only the northern part of Luzon, other regional satellite services have signed on with Palapa, which covers the Philippines. Additional services may emerge on future satellites covering the region as well.

Therefore, the question is how these foreign entrants into the domestic broadcasting "mix" should be handled from a regulatory standpoint. Further, domestic suppliers of video programming may also emerge as cable systems and TVROs become more widespread. No policies or regulations for these services currently exist.

4.6 Space Segment Availability

The Philippines has always relied upon the Indonesia satellite system, Palapa, for space segment capacity, since besides INTELSAT, few alternatives exist. However, new space segment capacity is expected to come on line in the region in the next several years. On the other hand, demand for space segment capacity from the five domestic satellite carriers and the broadcasters permitted to obtain their own capacity directly could soon put a strain on available capacity. Competition in other countries could also lead to a spurt in demand for available satellite capacity in the region.
The question here is whether DOTC should play a role in attempting to match Philippine satellite demand with supply. Should a shortage develop, the government would undoubtedly be quickly brought into the situation. Longer term, the question emerges whether the Philippines should consider obtaining its own satellite system, perhaps one of the "lightsats" now being promoted in some quarters. However, since the carriers are privately owned and DOTC plays an investors role in only one earth station network, the question would be, under what legal and organizational framework would such a satellite be procured and operated?

4.7 Role of the Government

The latter question leads directly into a larger one about the role the government should play in satellite communications. The DOTC is designated as the primary telecommunications policymaking body of the Government and the NTC as the regulator. Nevertheless, adjuncts of the Department have also traditionally been involved in operational matters and the recent MOU with CapWire will give the Department an investment, at least, in the satellite sector as well. Efforts need to be made to insure that this dual role does not create conflicts. After all, while the department's reason for entering into the joint

venture with CapWire is to promote the use of satellite communications to meet the communications needs of the country, the CapWire network will not accomplish this alone and the other domestic satellite carriers have a vital role to play in a competitive market.

In addition, however, the government as a user of satellite services needs to examine how this role can be fulfilled in a way that promotes the vitality of the domestic satellite sector. Further, the lessons learned elsewhere as to how to use satellite communications to extend educational and social services to rural and underdeveloped areas need to be reviewed for their applicability to the Philippine situation. The government would obviously have to take the lead in these efforts.

In the policymaking exercise which has been initiated, other issues may emerge, but these latter six would appear to be the core questions.

5.0 POLICY OBJECTIVES

The issues noted above require government attention, and their resolution will involve the balancing of conflicting interests. In this process, the options considered will be measured against the prime government policy thrust, namely growth, through the private sector, on a self-supporting basis, given the demand and funding constraints. Moreover, growth is most urgently required in remote and rural areas, where satellite communications may be the most cost-effective means of establishing links to the existing network infrastructure. It is vital, therefore, to ensure that the market is not burdened with too many operators, which would threaten the viability of the existing players, who are essential to the provision, at reasonable rates, of satellite services for rural applications. It is, therefore, a question of drawing a line between a competitive marketplace, as mandated, and the need to expand into marginal market areas, with a minimum of government involvement. This balancing act is no mean feat, and possibly unique in the telecom world for a developing country.

6.0 POLICYMAKING PROCESS

6.1 Staff Research/Consultant's Report

The first activity undertaken by the DOTC was to request the satellite service providers identified in the previous section of this Paper to provide the necessary information on the following topics:

- Brief history of the service provider including its facilities and the market currently served;
- Services offered and plans for the improvement/expansion of satellite communications systems;
- Issues regarding government regulation, proliferation of service providers and problems which hinder the development of satellite-based services;
- Recommendations on the coverage and the methodology in formulating the policy.

This undertaking was primarily aimed at assessing the present satellite communications structure and current issues to serve as a guide for the service providers, regulators and users of this service and facilities with the end view of preparing a Background Paper.

This activity was later supplemented. To this end, resources provided under the CIDA Technical Assistance Program have been assigned to work with DOTC Planning Staff, and USAID has provided added consulting assistance (later to be referred to as the Group). This Group has evolved an action plan, and the process is underway toward a draft policy for further discussion. Carriers and other stakeholders were approached for preliminary discussions, and a background paper was prepared based upon these inputs and other research.

6.2 Request for Public Comment

As part of the process of formulating a policy statement, the Department is scheduled to release very soon a Request for Information and Views to international and domestic voice, data, telegraph and telex carriers, as well as the present satellite carriers. Views will also be sought from broadcasting industry, various trade and business associations, academia, interested government agencies and the general public.
The purpose of the Request is to solicit information and opinions concerning the issues raised to date and to identify any other matters which may have been overlooked in the internal DOTC review. It also intends to verify the information that were collected concerning the current state of development of the domestic satellite industry.

A public reference file was created and is being maintained by the Department to contain a copy of the Request, all background materials gathered, all non-confidential information filed in response to the Request along with all opinions on policy matters.

6.3 Planned Issuance of Draft Background Paper/Options Paper

The information and views provided from the activities described in the preceding section will be used to develop a comprehensive background paper summarizing the information and issues identified, opinions expressed, and propose some tentative policy guidelines for the orderly development of satellite communications in the Philippines. The Department's target is to release this Background Paper for public review and comment early in 1992. This Background Paper will also be issued for public review and comment.

6.4 Release of Department Circular

The responses received by the Department will be analyzed and reviewed by the Group and policy recommendations would be made to the Telecommunications Policy Programs Review Committee (TPPRC), a committee created by the DOTC Secretary to provide high level review of all the Department's policy planning and implementation activities to ensure that the government's overall goals for the telecommunications sector are being met. With the TPPRC approval, the Secretary would then be briefed and asked to endorse and issue the policy. This policy would then form the basis for guiding future regulatory and other related decisions by the Government. If legislation were to be required, this too would be developed during the policy development process. The Department's target is to officially release the Department Memorandum Circular in April 1992.

The above process represents a first for the Department. The development of a policy through a consultative process is not new, but in this instance, it is intended to consult with all stakeholders, and then issue the government's policy in final form after due consideration of all inputs. As this process is developed, it is intended to form the basis for a policy-making model for the other issues confronting the TPPRC.

7.0 FUTURE APPLICATIONS OF POLICY PROCEDURES

The process employed in this matter is new to the Philippines. In the past, a consensus approach has been followed, sometimes successfully, especially on broad policy formulation. However, in recent years, this approach has been found wanting, since conflicting interests in a competitive environment make common ground on some issues difficult to find. The result has often been a stalemate, or worse, a "lowest common denominator" sort of policy statement. Such statements have been of little use to the regulator, NTC, which faces precisely the issues that the consensus process could not resolve. In the end, the regulator had to act without policy guidance.

This process seems lengthy, and will open up more issues that some parties do not wish to see resolved by the government. Moreover, there may be pressure on the government to avoid making policy, from those who are served best by the status quo. This will be a necessary part of the process, and must be managed by the policy body. The issue of confidentiality is also new to this process, and it is not clear whether the parties "trust" the process enough to reveal to the department sensitive marketing information.

The above problems notwithstanding, it is believed that this approach could be successfully applied to a number of national telecommunications issues currently under study. They include:

- cellular radio policy;
- ratemaking issues (unbundling, customer provided terminals, resale etc.)

The objective of the process, when one considers the scarcity of skilled staff, and the workload on government officials, is to harness the energies of the private sector parties who have a stake in the process. They will be encouraged to the raw material on which informed policy choices can then be made. Time will tell.

Author Biodata

Engr. Aurora A. Rubio joined the DOTC as a supervising communications development officer in 1989. She was project manager for the ADB-funded National Telecommunications Development Plan (NTDP) project. In addition to ongoing responsibility for the NTDP, she is national coordinator for the UNDP/ITU Telecommunications Management Development and Training project, and supervises the Telecommunications Policy Planning Section of the DOTC.

Stuart C. MacPherson is an electrical engineer employed by Teleconsult ltd., an engineering and management consulting firm based in Vancouver, Canada, specializing in telecommunications. He is involved in the technical assistance project funded by the Canadian International Development Agency supporting the Philippine government on various policy and regulatory issues and the deployment of a Canadian-funded rural telephone system.

Timothy J. Logue is a Space & Telecommunications Analyst with the Washington, D.C. office of Reid & Priest. He has been assisting in the domestic satellite policymaking process under a contract with the U.S. Agency for International Development.

Lessons drawn from 2 existing regional satellite networks : ARABSAT and EUTELSAT. Application to the Pacific Basin projects

Jean-Jacques BLOCH
Aerospatiale
06322 CANNES, FRANCE

1. ABSTRACT

Two regional satellite networks have been in operation for more than 6 years «ARABSAT and EUTELSAT». After a brief description of each system, the current use of their payload is reviewed and compared with their respective planning stage predictions. From this perspective, some teachings are drawn which could be profitable for emerging regional Pacific Basin networks, now in the planning stage.

2. DESCRIPTION OF TWO EXISTING SATELLITE NETWORKS

2.1. ARABSAT

This network belongs to the ARABSAT organisation which includes more than 20 countries of the Arab League.

A contract was signed with AEROSPATIALE as prime contractor in 1981 for the construction of 3 spacecraft. The first two were launched in 1985 i.e. ARABSAT 1A with ARIANE in February 85, ARABSAT 1B with the U.S. Shuttle in June 1985.
The third model, ARABSAT 1C will be launched in early 92 with ARIANE.

The payload consists in 25 channels at C-band (33 MHz bandwidth each) plus an S-band channel. The nominal coverage as shown in figure 1 is a shaped beam at C-band and an elliptical area at S-band.

The edge of coverage EIRP at C-band is 31 dBW (center : 34 dBW) and 41 dBW at S-band (center 45 dBW). 1A is located at 19° East longitude, 1B at 26° East (see coverage at figure 2).

The main ground control station is located near Ryadh in Saudi Arabia while a back-up station is situated near Tunis in Tunisia.

2.2. EUTELSAT

The EUTELSAT organization is based on the INTELSAT model, its membership being limited to European PTT's. Presently 29 countries are involved. Its space capacity includes two generations of satellites.

The first one, EUTELSAT I, is composed of 4 spacecraft, launched between 1983 and 1988. Each satellite includes up to 12 Ku-band channels covering Europe in 3 spot beams and 2 wider beams (fig.3) with an EIRP of 39 dBW at the edge (45 dBW at center). Presently, 3 models are still active.

The second generation, EUTELSAT II, is composed of at least 6 satellites contracted with AEROSPATIALE as prime contractor. The first one was launched in August 1990 while the second was launched in January 1991.
By mid-1992, 4 such models will be on orbit.

The payload consists of 16 Ku-band channels with higher EIRP.
The coverage (figure 4A and 4B) can be switched between a large European area, with an edge EIRP of 44 dBW and a narrow central Europe beam, with an edge EIRP of 50 dBW (center 52 dBW). This flexibility is available by ground command to any channel. The satellites are controlled from the headquarters of the organization located in Paris, France.

3. CURRENT USE OF THESE NETWORKS

3.1. ARABSAT USAGE

As of November 1991, ARABSAT 1A was used by several Arab countries while ARABSAT 1B is partly leased to India which occupies four half-transponder channels for India Television. On ARABSAT 1A, 5 channels are occupied by full-time national television programs of Saudi Arabia (2), Oman, Morocco and Mauritania while 2 more are used for occasional-use TV service.

Concerning regional Telephony (FDM/FM or SCPC traffic), present loading is about 35 % of the capacity set aside for this purpose. Domestic telephony loading is also fairly low as compared to capacity.

Finally, the S-band channel has been switched on in November 1990, it carries the Egyptian domestic TV program.

3.2. EUTELSAT CAPACITY USAGE

Here is the current transponder loading status (see fig.5) in number of transponders.

EUTELSAT I at 7° East (F4)
8 TV channels with radio programs on sub-carriers .
1 business communication (SMS)
2 occasionnal TV
1/2 EUTELTRACS

EUTELSAT II at 10° East (F2)
5 TV channels + occasional TV
4 business communications (SMS)
1 closed user group (French racing channel)
1 domestic telephony (Denmark)

EUTELSAT II at 13° East (F1)
8 TV channels + radios (13 programs)

EUTELSAT I at 16° East (F1)
(on inclined orbit)
1 EUTELTRACS

EUTELSAT I at 21.5° East (F5)
2 Regional TV (EBU)
6 TDMA telephony
3 occasional TV

4. COMPARISON WITH DESIGNER PROJECTIONS

In the case of EUTELSAT, the design of the first generation satellites occured in the late seventies. At that time, television in Europe was still ruled by state monopolies and the bulk of satellite occupancy was predicted to be regional digital telephony and broad band-business services (all channels were 72 MHz wide).

However these projections did not materialized (see figure 6), the business services had a slow start, partly due to the high fees asked for wideband teleconferencing and high bit rate data transmission.
On the other hand most western European countries gave up their television monopolies during the 80"s and scores of commercial television companies sprung up, eager to reach the wide audience accessible via satellite transmission. This trend was taken into account for the design of the second generation satellites (EUTELSAT II) where 9 out of the 16 channels are 36 MHz wide and where the coverage can be zoomed on a narrow, high EIRP, beam (called «superbeam») enabling individual reception of TV channels using 80 cm. dish .
Recently, a new commercial service, not envisaged at the design stage of the EUTELSAT satellites has been launched, dubbed EUTELTRACS, it consists of a land mobile service providing two-way message exchange and position reporting for vehicles anywhere within the satellite coverage (the signals from the mobile to the base station are up-linked in a dedicated 36 MHz bandwidth, the base to mobile link takes up another 2 MHz bandwidth).Two satellites are involved for positionning (see figure 5).

South of Europe, in the Arab states, the national television monopolies did not break up, moreover law-makers, there, are not inclined to let western style programming reach the general public. Therefore ARABSAT did not undergo the tremendous TV capacity demand increase observed with EUTELSAT. Thus, although, the original motivation for ARABSAT came from the national broadcasters of the Arab States Broadcasting Union (ASBU), the backbone use of the system became telecommunications.

The fairly low filling ratio of ARABSAT transponders has several causes among which :

- the communication ground antenna in the various member countries were put into service very slowly and generally several years after theoritical start of the system,

- the rates are comparable to, rather than, competitive with INTELSAT,

- contrary to expectation there is not a high degree of inter-Arab traffic, most of the international traffic appears to be going over INTELSAT to other countries.

In summary in both cases, about ten years after design, the distribution of services is not what was projected, the obvious conclusions is to achieve flexibility in satellite payload to cope with market evolution.

5. SITUATION IN THE PACIFIC BASIN

In the Pacific Basin several private and governmental regional satellite networks either newly existing or in the design phase are vying to deliver services to potential customers. Theses services include national Television, commercial Television, VSAT networks, and regional or domestic telephony.

The countries involved in most coverages of these systems are not as much related as say European Countries on one side, the Arab States on the other.

For example the legislation for television provision is very different in Burma/China and Thailand/Taiwan - all countries included in the coverage area of ASIASAT 1.
Still, Television is considered as the most promising money making service, while point to point telephony has to keep into account the competition of optical fibers throughout the area. Otherwise VSAT networks will only interest fairly developed nations and many of these networks are needed to fill up a transponder while only one is necessary with Television (a 36 MHz wide transponder is assumed).

Although happening in another part of the world, the experience gained with the two regional systems described previously, ARABSAT and EUTELSAT, should be used to lay down some general principles.

Therefore the following considerations should be kept in mind for those in charge of designing the payload of future similar satellite systems or trying to assess potential markets :

- keep flexibility in the payload (transparent transponder, steerable beam),

- Television is likely to be the backbone service for capacity loading and revenue making,

- countries with liberal TV provision policies should be marketed heavily,

- set the transponder lease rate at a competitive level with respect to INTELSAT,

- catch the market of world wide TV network (e.g. CNN),

- do not expect telephony either trunk routes or thin routes to take up much loading (Major routes are already installed with optical fibers and thin route is hardly a contender to fill up capacity),

- Also, communication ground station availability has proved to take time and alter many a business plan.

THE TONGASAT ASIA-PACIFIC REGIONAL SATELLITE COMMUNICATIONS NETWORK

DR. MATS C. NILSON, MANAGING DIRECTOR, TONGASAT, AND
MR. SIONE KITE, DEPUTY CHIEF SECRETARY AND DEPUTY SECRETARY TO CABINET, PRIME MINISTER'S OFFICE
KINGDOM OF TONGA

ABSTRACT

THIS PAPER DESCRIBES THE ADVANTAGES THAT ARE ENJOYED BY USERS OF THE TONGASAT ASIA-PACIFIC SATELLITE SYSTEM AND ILLUSTRATES THAT ALL COUNTRIES WITHIN THE COVERAGE AREA CAN PARTICIPATE, WITHOUT MAKING FINANCIAL CONTRIBUTIONS.

WITH RAPIDLY GROWING TRADE, AIR TRAFFIC AND TOURISM, THE ASIA-PACIFIC REGION OF THE WORLD IS EXPERIENCING ENORMOUS INCREASES IN THE NEED FOR SEVERAL TYPES OF TELECOMMUNICATIONS SERVICES. *THE ASIA-PACIFIC REGION COMPRISES WELL OVER 100 DISTINCT GEOGRAPHICAL JURISDICTIONS*, WITH A TOTAL POPULATION IN EXCESS OF THREE BILLION PEOPLE.

RURAL AND INTER-ISLAND COMMUNICATIONS REQUIREMENTS ARE OF INCREASING ECONOMIC IMPORTANCE TO A NUMBER OF COUNTRIES IN THE ASIA-PACIFIC REGION. THESE NEED TO BE SERVED VIA SATELLITE NETWORKS USING SMALL, INEXPENSIVE EARTH STATIONS (SOMETIMES CALLED "VSAT'S"). CABLE OR RADIO LINKS ARE TOO EXPENSIVE AND TAKE A LONG TIME TO CONSTRUCT.

IT IS ANTICIPATED THAT THE INTERNATIONAL TELECOMMUNICATIONS SATELLITE ORGANIZATION, INTELSAT, THE COMMERCIAL INTERNATIONAL SATELLITE OWNER AND OPERATOR ORGANIZATION, WHICH CURRENTLY ADMIRABLY PROVIDES NEARLY ALL INTERNATIONAL SATELLITE TELECOMMUNICATIONS TRAFFIC IN THE ASIA-PACIFIC REGION, MAY NOT BE ABLE TO SATISFY THE INCREASE IN DEMAND FOR TELECOMMUNICATIONS CAPACITY IN THAT REGION IN THE LATE 1990'S. IN PARTICULAR, INTELSAT WILL PROBABLY NOT BE ABLE TO ACCOMMODATE TRUE VSAT EARTH TERMINAL OPERATION THROUGHOUT THE ASIA-PACIFIC AREA.

COMPETITION IN TELECOMMUNICATIONS SERVICES HAS PROVEN BENEFICIAL TO END USERS AND CONSUMERS IN COUNTRIES WHERE COMPETITION HAS BEEN INTRODUCED. SUBSCRIBERS USUALLY BENEFIT IN TERMS OF LOWER PRICES FOR THEIR CALLS. IN ADDITION, ALTERNATE OR REDUNDANT PATH FACILITIES ARE VERY MUCH DESIRED BY MANY TELECOMMUNICATIONS CARRIERS, USERS, GOVERNMENT AGENCIES AND MILITARY THROUGHOUT THE WORLD.

FEATURES OF TONGASAT

- BROAD REGIONAL COVERAGE TO REACH HUGE MARKET AREA
- SAME EARTH STATIONS FOR DOMESTIC AND INTERNATIONAL TRAFFIC
- BY - PASS TERRESTRIAL NETWORK
- INEXPENSIVE SMALL COMMUNITY AND CUSTOMER PREMISE STATIONS (PARKING LOT, ROOF TOP, DRIVE-WAY)
- ACCESS FROM RURAL AREAS
- INTER-ISLAND COMMUNICATIONS
- CULTURAL/EDUCATIONAL TV DISTRIBUTION

Transportable Ku-Band Satellite Uplink Services

DUE TO THE ABOVE FACTORS, MOST FORESIGHTED TELECOMMUNICATIONS PLANNERS IN THE ASIA-PACIFIC REGION BELIEVE THAT ANOTHER SATELLITE SYSTEM IS NEEDED, CAPABLE OF SERVING THE WHOLE AREA, FROM THE SAUDI PENINSULA, IRAN AND PAKISTAN IN THE WEST TO HAWAII AND TAHITI IN THE EAST, AND FROM CHINA, KOREA, THE USSR AND JAPAN IN THE NORTH TO AUSTRALIA AND NEW ZEALAND IN THE SOUTH. ALL JURISDICTIONS IN BETWEEN THESE EXTREMES NEED OF COURSE ALSO BE SERVED, INCLUDING ALL OF THE PACIFIC ISLAND COUNTRIES AND TERRITORIES.

IN ADDITION, SOME BUSINESS AND GOVERNMENT CUSTOMERS IN THE ENTIRE REGION NEED DIRECT COMMUNICATIONS LINKS TO THE WEST COAST OF THE UNITED STATES AND TO EUROPE, EVEN FROM RURAL OR ISLAND AREAS, MOST OF WHICH HAVE NO SUCH LINKS TODAY.

DESIGNED AND PLANNED AS THE IDEAL ANSWER TO ALL THESE REQUIREMENTS, THE TONGASAT REGIONAL SYSTEM WILL PROVIDE THE ULTIMATE IN FLEXIBILITY FOR ANY USER IN THE ENTIRE ASIA-PACIFIC REGION. TONGA HAS REGISTERED WITH THE ITU/IFRB IN GENEVA A TOTAL OF SIX ORBITAL POSITIONS FOR THE REGIONAL SYSTEM NEEDS. THESE CAN ACCOMMODATE UP TO 20 SATELLITES TO MEET VARIOUS NETWORKING REQUIREMENTS.

ONE OF THE MAJOR ADVANTAGES INHERENT IN POSESSING SIX POSITIONS IS THAT *THE TONGASAT SYSTEM NOT ONLY WILL PROVIDE THE LUXURY OF SERVING THE WELL OVER 100 JURISDICTIONS WITHIN THIS VAST ASIA-PACIFIC AREA, BUT WILL ALSO PROVIDE IDEAL SATELLITE LOCATIONS FOR TRANS-PACIFIC LINKS AND FOR LINKS WITH EUROPE TO THE ASIA-PACIFIC REGION.*

TO ILLUSTRATE THIS, THE EAST TONGASAT ORBITAL POSITION IS IDEAL FOR NETWORKS SERVING PACIFIC ISLAND COUNTRIES AND FOR HIGH DENSITY TRAFFIC STREAMS BETWEEN THE WEST COAST OF THE UNITED STATES AND THE PACIFIC RIM COUNTRIES.

ANOTHER TONGASAT ORBITAL POSITION HAS BEEN CAREFULLY SELECTED TO *CONNECT TRAFFIC FROM EUROPE TO ALL ASIA-PACIFIC AND THE WESTERN PACIFIC RIM COUNTRIES, INCLUDING JAPAN AND THE WHOLE AUSTRALIAN CONTINENT.* MOST OTHER SATELLITES ARE NOT IN A POSITION TO COVER AUSTRALIA AND JAPAN, WHILE CONNECTING DIRECTLY WITH EUROPEAN COUNTRIES.

THE FOUR "CORE" ORBITAL POSITIONS OF TONGA HAVE BEEN VERY CAREFULLY SELECTED TO ENABLE THE TONGASAT REGIONAL SATELLITE SYSTEM TO REACH DIRECTLY TO HAWAII TO SERVE NORTH AMERICA, *INTERCONNECTING DIRECTLY WITH THE NORTH AMERICAN NETWORK*, WHILE THE SATELLITES WILL BE POSITIONED IN ORBIT IN SUCH A MANNER THAT THEY CAN SIMULTANEOUSLY SERVE THE WELL OVER 100 OTHER JURISDICTIONS IN ASIA-PACIFIC.

REALITY

TRADE IS GROWING

INTRA ASIA - PACIFIC NEED FOR TELECOMMUNICATIONS IS INCREASING

NEED FOR RURAL AREA COMMUNICATIONS IS URGENT

NO EXISTING SYSTEM CAPABLE OF PROVIDING LOW COST DATA COMMUNICATIONS

TOURISM IMPORTANT TO ECONOMIC GROWTH IN ASIA-PACIFIC

TOURISM IS MAJOR CONTRIBUTOR TO ECONOMIES

ASEAN COUNTRIES ALONE ESTIMATE 17 MILLION ARRIVALS IN 1990

ASEAN ANNUAL FOREIGN EXCHANGE RECEIPTS MORE THAN $15 BILLION

WORLD TOURISM WILL EXCEED 600 MILLION ARRIVALS BY YEAR 2000

TOURISTS WILL SPEND MORE THAN $500 BILLION/YEAR BY YEAR 2000

ASEAN - MALAYSIA, SINGAPORE, INDONESIA, THAILAND, PHILIPPINES, BRUNEI

THE TONGASAT ASIA PACIFIC REGIONAL COMMUNICATIONS SATELLITE SYSTEM IS DESIGNED TO PROVIDE EITHER DOMESTIC OR INTERNATIONAL CAPACITY, IN ACCORDANCE WITH THE NEED OF EACH INDIVIDUAL COUNTRY. *IF A COUNTRY BEGINS WITH DOMESTIC SERVICES, THE SAME SMALL EARTH STATIONS ITS CARRIERS OR USERS INSTALL INITIALLY CAN LATER INTERCONNECT TO INTERNATIONAL DESTINATIONS VIA THE TONGASAT SATELLITES.* HERETOFORE, SEPARATE EARTH STATIONS HAVE BEEN NECESSARY, ADDING AN INFRASTRUCTURE EXPENSE BURDEN, WHICH WILL NO LONGER BE PRESENT OR REQUIRED WITH TONGASAT'S REGIONAL SYSTEM.

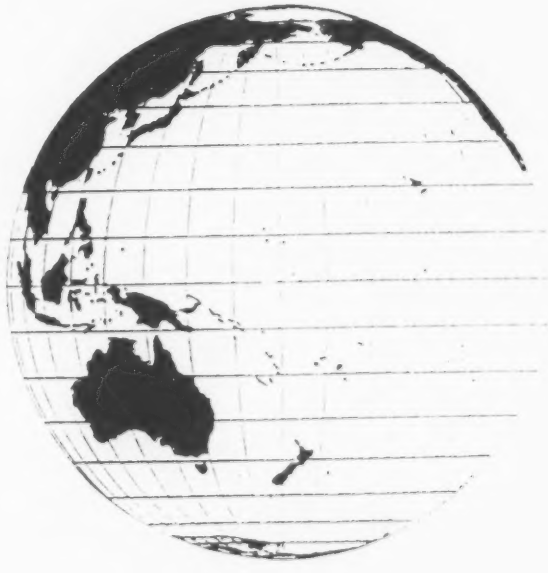
THE GOVERNMENT OF THE KINGDOM OF TONGA, AN INDEPENDENT, SMALL, NEUTRAL SOUTH PACIFIC ISLAND COUNTRY WITH A POPULATION OF ABOUT 100,000 IS FULLY SUPPORTING THE CREATION OF THE TONGASAT REGIONAL SYSTEM. TONGA FEELS THAT THE REGIONAL SYSTEM WILL BE OF BENEFIT TO ALL PARTICIPANTS.

IDEAL PARAMETERS

- HIGH ELEVATION ANGLES IN ASIA
- BROADEST GEOGRAPHICAL COVERAGE
- C-BAND FOR RAINY CLIMATES
- KU-BAND FOR SOME DOMESTIC USE
- HIGH POWER TO USE SMALL EARTH STATIONS
- ACCESS TO NORTH AMERICA VIA HAWAII

asia - pacific

THE EARTH AS SEEN BY THE TONGASAT SATELLITE AT 130 DEGREES EAST LONGITUDE



THE EARTH AS SEEN BY THE TONGASAT SATELLITE AT 171 DEGREES EAST LONGITUDE

WHY AN ASIA-PACIFIC SYSTEM?

WHY HAVE TONGA AND TONGASAT INVITED ALL THE TELECOMMUNICATIONS PROVIDERS IN ALL COUNTRIES OF THE ASIA-PACIFIC REGION TO PARTICIPATE IN THE USE AND OWNERSHIP OF A NEW SATELLITE SYSTEM FOR THE REGION?

WHY IS A NEW SATELLITE SYSTEM FOR THE ASIA-PACIFIC REGION SO DESIRABLE?

BECAUSE:

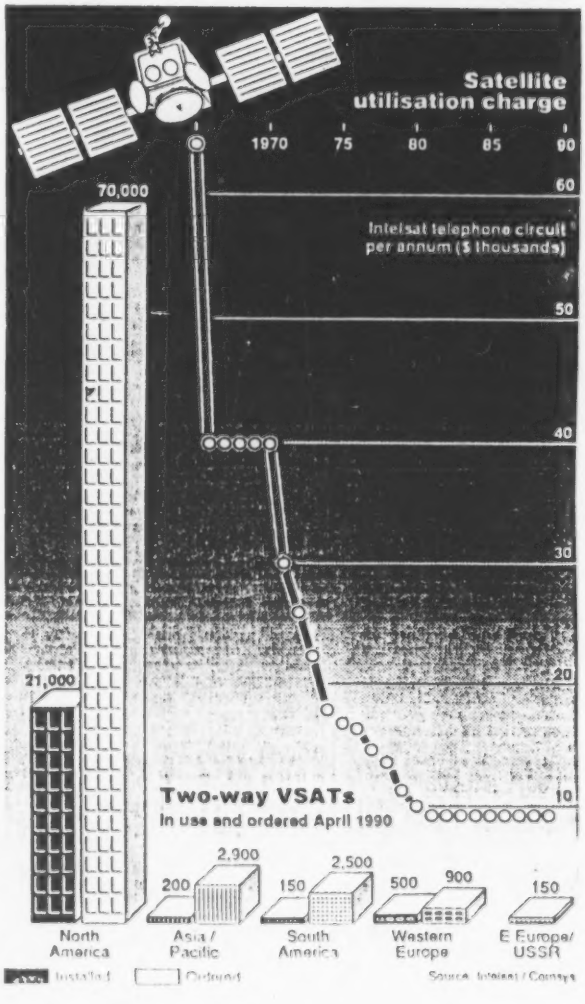
--THE ASIA-PACIFIC REGION IS DEPRIVED IN TERMS OF SATELLITE TELECOMMUNICATIONS, ESPECIALLY WHEN COMPARED TO NORTH AMERICA, SOUTH AMERICA AND TO EUROPE. SATELLITE COMMUNICATIONS LINKS ARE VERY LIMITED BY COMPARISON TO THE RELATIVE POPULATIONS OF THESE PARTS OF THE WORLD. SMALL EARTH STATION (VSAT) SATELLITE NETWORKS ARE NOT WIDESPREAD IN THE ASIA-PACIFIC AREA, PARTLY DUE TO OVER-REGULATION BY GOVERNMENTS, PREVENTING THE CREATION OF OPTIMIZED REGIONAL INTERNATIONAL SYSTEMS, RESULTING IN LACK OF SUITABLE SATELLITE CAPACITY. AN ARTICLE IN THE LONDON FINANCIAL TIMES OF 17 JULY 1990 POINTS OUT THAT *THE NUMBER OF SATELLITE VSAT TERMINALS IN USE AND ORDERED FOR INSTALLATION IN THE ASIA-PACIFIC REGION IS DIRECTLY INVERSE TO THE RELATIVE POPULATIONS, WHEN COMPARED TO NORTH AMERICA AND EUROPE.*

--IN FACT, *NOT ONLY IS THE COMPARATIVE VSAT POPULATION INVERSE TO THE PEOPLE POPULATION, BUT SO IS THE NUMBER OF SATELLITE TRANSPONDERS IN USE IN THE ASIA-PACIFIC REGION WHEN COMPARED TO THE POPULATION* OF NORTH AMERICA -- ANOTHER FACTOR CONTRIBUTING TO LIMITING THE GROWTH OF INDUSTRY, TOURISM, TRADE AND GNP IN ASIA-PACIFIC. *THE REGION IS IN NEED OF MORE TELECOMMUNICATIONS FACILITIES TO PROMOTE GROWTH IN THESE IMPORTANT AREAS OF DEVELOPMENT.*

--SOME ASIA-PACIFIC COUNTRIES HAVE TREMENDOUS PROBLEMS COPING WITH THE OVER-CROWDING OF THEIR CAPITAL AND OTHER LARGE CITIES. THE TONGASAT REGIONAL COMMUNICATIONS SYSTEM CAN HELP STOP AND EVEN REVERSE THIS RELENTLESS MIGRATION FROM THE RURAL AND ISLAND AREAS. GOOD COMMUNICATIONS WILL ENABLE FACTORIES, REGIONAL OFFICES AND TRADING COMPANIES AND VARIOUS INDUSTRIES TO RE-LOCATE IN THE COUNTRY-SIDE. PLANTATIONS AND FISH FARMS CAN FLOURISH. EMPLOYERS BENEFIT BY HIRING HONEST AND HARD WORKING RURAL LABOR AND BY HAVING RELIABLE COMMUNICATIONS.

--ONE OF THE FOREMOST REASONS IS THAT MANY NATIONS IN THE ASIA-PACIFIC COVERAGE AREA HAVE REQUIREMENTS FOR RURAL OR INTER-ISLAND TELECOMMUNICATIONS LINKS THAT CANNOT ECONOMICALLY AND QUICKLY AND EASILY BE IMPLEMENTED WITHOUT POWERFUL COMMUNICATIONS SATELLITES, WHICH PERMIT SMALL AND INEXPENSIVE EARTH STATIONS (VSAT'S) TO BE USED, EITHER FOR DOMESTIC OR FOR INTERNATIONAL PURPOSES.

FINANCIAL TIMES TUESDAY JULY 17 1990



--AN IMPORTANT REASON IS THAT IT IS OF ADVANTAGE TO CARRIERS OR PROVIDERS OF COMMUNICATIONS LINKS TO HAVE AVAILABLE "ALTERNATE FACILITIES", ESPECIALLY FOR INTERNATIONAL LINKS. THIS "PATH DIVERSITY" IS ALSO OFTEN OF INTEREST TO MILITARY AUTHORITIES.

COMPETITION IN THE PROVISION OF TELECOMMUNICATIONS CARRIERS AND THEIR FACILITIES HAS ALWAYS RESULTED IN BENEFITS TO THE END-USERS OF COMMUNICATIONS IN THOSE COUNTRIES WHERE SUCH COMPETITION HAS BEEN INTRODUCED. NORMALLY, END USER CHARGES ARE LOWERED AS COMPETITION IS INTRODUCED.

--MOST POWERFUL OF ALL REASONS IS PERHAPS THAT A UNITED APPROACH OF SEVERAL COUNTRIES WILL TAKE ADVANTAGE OF THE ECONOMY OF SCALE SO NECESSARY TO MAKE VIABLE A COMMUNICATIONS SYSTEM COSTING HUNDREDS OF MILLIONS OF US DOLLARS.

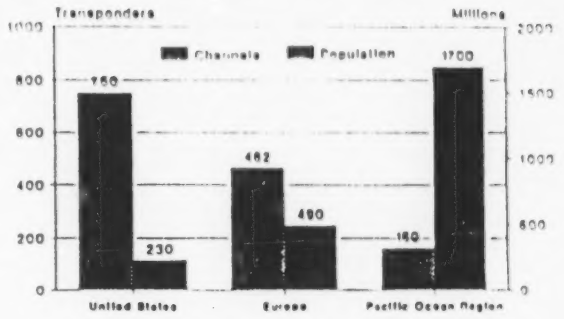
--NOT LEAST IS THE REASON THAT INTELSAT, WHICH ADMIRABLY PROVIDES SATELLITE COMMUNICATIONS SERVICES TO MOST OF THE WORLD'S NATIONS, MAY NOT BE ABLE TO PROVIDE ENOUGH SATELLITE CAPACITY OF THE TYPE NECESSARY TO SERVE THE GROWING NEEDS OF THE ASIA-PACIFIC REGION IN THE LATE 1990'S, PARTICULARLY NOT TO THOSE COMMERCIAL AND GOVERNMENTAL USERS IN EACH COUNTRY THROUGHOUT THE ASIA PACIFIC REGION, WHO WISH TO EMPLOY THEIR OWN SMALLER CUSTOMER PREMISE OR COMMUNITY EARTH STATIONS (VSAT'S). THIS IS BECAUSE INTELSAT SATELLITES WERE NOT OPTIMIZED FOR, AND ARE THEREFORE NOT ECONOMICAL FOR, USE WITH SUCH SMALL EARTH STATIONS.

--THERE WILL BE AMPLE DEMAND DURING THE 1990'S TO WARRANT INTRODUCTION OF A SECOND SATELLITE NETWORK, WHICH WILL ALSO SERVE TO PROVIDE ALTERNATIVE COMMUNICATIONS FACILITIES TO END-USERS OF PARTICIPATING NATIONS IN THE REGION.

--THERE IS NEED FOR ADDITIONAL CAPABILITY TO REACH OUTLYING ISLANDS OR RURAL AREAS WITH CULTURAL AND EDUCATIONAL TV, ENTERTAINMENT AND NEWS TV PROGRAMMING, USING SMALL, INEXPENSIVE TV RECEIVE EARTH STATIONS (TVRO'S).

--FINALLY, THE ECONOMIC ADVANTAGES TO SUBSCRIBERS AND BUSINESS END-USERS OF ELIMINATING IN MOST INSTANCES THE EXPENSIVE LAND-LINE CONNECTIONS TO REACH DISTANT EARTH STATIONS IS VERY IMPORTANT IN SOME COUNTRIES. AS AN EXAMPLE, FOR USERS WITH HIGH DATA RATE DIGITAL DATA TRANSMISSION REQUIREMENTS, DOMESTIC TERRESTRIAL MICROWAVE OR RADIO RELAY FACILITIES ARE OFTEN EITHER NOT CAPABLE OF SUCH TRANSMISSIONS OR THEY ARE NON-EXISTENT.

Transponder/Population



ASIA-PACIFIC " MEGA - CITIES "
FACE BIG PROBLEMS

WORSENING POLLUTION AND CRUSHING POPULATION GROWTH

URBAN POPULATION GROWTH OF 3% TO 6.5% PER YEAR - 3 TIMES FASTER THAN IN VILLAGES

BY 2020 HALF OF ASIA-PACIFIC POPULATION IN " MEGA - CITIES "

BY 2000 ASIA-PACIFIC URBAN POPULATION 1.157 BILLION PEOPLE

52 " MEGA - CITIES " IN ASIA-PACIFIC BY YEAR 2025

UNEMPLOYMENT, GARBAGE, SMOG, LEAD, CARBON, SULPHUR DIOXIDE

ADVANTAGES OF TONGASAT

AN INTERNATIONAL PARTNERSHIP CALLED THE "INTERNATIONAL OWNERSHIP BODY, (IOB)", WILL OWN AND OPERATE THE REGIONAL SATELLITE SYSTEM USING THE SIX ORBITAL POSITIONS OF THE KINGDOM OF TONGA. TONGASAT WILL OWN 10% OF THE IOB, AND THE REMAINING PARTNERS 90%. THUS NEITHER TONGA NOR TONGASAT ARE DOMINANT IN THE IOB.

PARTICIPATION IS VERY FLEXIBLE. IOB PARTNERS MAY BE COMMERCIAL OR GOVERNMENTAL ORGANIZATIONS. THEY CAN BE INVESTORS WHICH ARE NOT SIGNATORIES. ALTHOUGH MOST ARE EXPECTED TO BE SIGNATORIES, IT SHOULD BE CLEAR THAT INVESTORS NEED NOT BE SIGNATORIES OF PARTICULAR COUNTRIES. FURTHERMORE, A SIGNATORY, WHICH IS APPOINTED THE FRANCHISEE LICENSED TO CARRY TRAFFIC IN AND OUT OF ITS COUNTRY, CAN BE A NON-INVESTING SIGNATORY.

INITIAL INVESTMENTS NEED COVER INITIAL PAYMENTS FOR CONTRACTS. THE IOB PARTNERS WILL HAVE THE LUXURY OF BEING ABLE TO PHASE THEIR TOTAL CAPITAL COMMITTMENTS AS FUNDS ARE REQUIRED FOR SATELLITE AND LAUNCH SERVICES CONTRACTS OVER 1992 TO 1996, FOR THE FIRST GENERATION OF THREE SATELLITES.

THUS, RELATIVELY LOW INITIAL INVESTMENTS ON THE PART OF THE IOB PARTNERS WILL RESULT IN THE FOLLOWING ADVANTAGES, BY JOINING THE TONGASAT REGIONAL SYSTEM VERSUS JOINING OTHER POTENTIAL SYSTEMS VYING FOR A ROLE IN THE ASIA-PACIFIC REGION OR FOR THE PACIFIC RIM COUNTRIES:

- TONGASAT GUARANTEES *MAXIMUM FLEXIBILITY* OF PLACEMENT OF FUTURE SATELLITES, DUE TO AVAILABILITY OF SIX ORBITAL POSITIONS OF TONGASAT, ABLE TO ACCOMMODATE UP TO 20 "LIGHT-SATS" OR UP TO 12 MEDIUM WEIGHT SATELLITES -- WHICH IN TURN PROVIDES THE *ABILITY TO MEET ANY CUSTOMER REQUIREMENTS* THROUGHOUT THE ASIA-PACIFIC REGION, DUE TO THE GEOGRAPHICAL PLACEMENT POSSIBILITES OF SATELLITES

- THE IOB PROVIDES FOR SHARING OF THE INVESTMENT CAPITAL REQUIRED WITH NEW PARTNERS ACCEPTABLE TO THE INITIAL PARTNERS AND TO TONGASAT

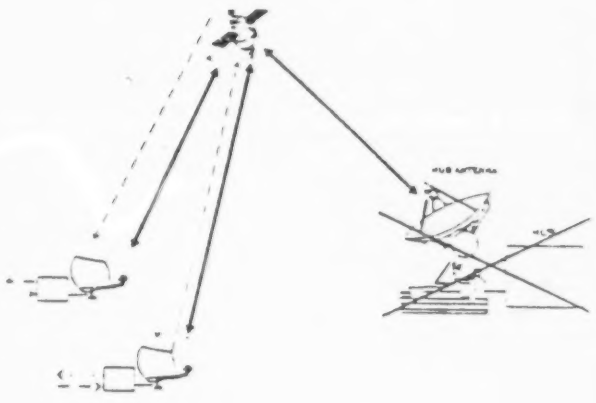
- THE INITIAL CAPITAL INVESTMENT OF THE FIRST IOB PARTNERS, FOR 90% OF THE IOB PARTNERSHIP, OR SMALLER PERCENTAGES THEREOF, CAN BE SOLD TO OTHER ENTITIES THAT WISH TO BECOME PARTNERS IN OR INVESTING SIGNATORIES TO THE IOB, DURING THE SATELLITE CONSTRUCTION PERIOD, OR THEREAFTER, WITH PROBABLE LARGE PROFITS TO THE INITIAL PARTNERS

- PROVIDERS OF NETWORK SERVICES, DOMESTIC SATELLITE SERVICES, TV DISTRIBUTION, RADIO NETWORKS, CNN, BBC, ASIAN TV NETWORKS, CABLE SYSTEMS, VALUE ADDED NETWORKS, MULTINATIONAL COMPANIES, BANKS, FINANCIAL INSTITUTIONS, GOVERNMENT AGENCIES AND THE MILITARY, ETC. WILL JOIN THE TONGASAT SYSTEM, BECAUSE OF ITS VAST COVERAGE AND NUMBER OF SATELLITE POSITIONS. IN DOING SO, THEY *TAKE ADVANTAGE OF THE ECONOMY OF SCALE*, ASSURING BETTER:

  - SPARING IN ORBIT - OUTAGE PROTECTION
  - COVERAGE FLEXIBILITY
  - CONTINUED GROWTH
  - POSSIBILITY OF USING ALTERNATIVE PATHS
  - REDUNDANCY IN LARGER SATELLITES

- IN ADDITION TO THE *OPTIMUM COVERAGE OF FOUR "C-SAT"*

VSAT to VSAT Direct



VSATs

NO "HUBBING" OF V-SAT TRAFFIC

400

ORBITAL POSITIONS IN THE 130.0E TO 142.5E ARC, WITH HIGH ELEVATION ANGLES SPANNING OVER THE CENTERS OF POPULATION OF CHINA, JAPAN AND THE USSR IN THE NORTH TO AUSTRALIA IN THE SOUTH, PLUS COVERING FROM THE ARABIAN GULF IN THE WEST TO HAWAII AND TAHITI IN THE EAST, ALL INTERCONNECTED DIRECTLY TO THE NORTH AMERICAN NETWORKS VIA HAWAII, THE TONGASAT SYSTEM OFFERS ADDITIONAL SATELLITE POSITION ADVANTAGES:

- INTERCONNECTION WITH ALL COUNTRIES IN THE ENTIRE WESTERN PACIFIC RIM, DIRECTLY FROM THE WEST COAST OF THE UNITED STATES, THROUGH THE USE OF THE 170.75E POSITION IN C-BAND AND

- *PROVISION OF THE HIGHEST POSSIBLE ELEVATION ANGLES FOR THE PACIFIC AREA* THROUGH THE USE OF THE 170.75E C-BAND POSITION

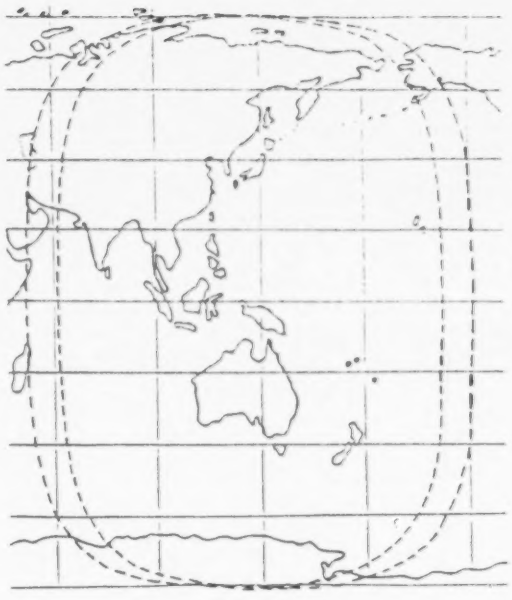
- INTERCONNECTION WITH EUROPE DIRECTLY FROM ALL WESTERN PACIFIC RIM COUNTRIES, *INCLUDING JAPAN AND THE WHOLE AUSTRALIAN CONTINENT*, AND FROM ALL COUNTRIES BETWEEN EUROPE AND THE WESTERN PACIFIC RIM NATIONS, VIA THE USE OF THE 83.3E POSITION IN Ku-BAND

- BEST POSSIBLE HIGH EARTH STATION ELEVATION ANGLES IN EAST ASIA/AUSTRALIA/NEW ZEALAND/PNG/CHINA/TAIWAN/JAPAN/HK AND IN THE PHILIPPINES FOR BUSINESS COMMUNICATIONS SYSTEMS USING SMALL EARTH STATIONS -- *MAKES INSTALLATION OF EXTENSIVE NETWORKS FAR LESS EXPENSIVE THAN IF SATELLITES ARE LOCATED FAR TO THE WEST OR FAR TO THE EAST IN ORBIT* -- EASES INSTALLATION OF THOUSANDS OF EARTH STATIONS

- *ECONOMY OF SCALE, BOTH IN TERMS OF SPACE SEGMENT AND GROUND SEGMENT, WILL EVENTUALLY ENABLE THE TONGASAT ASIA-PACIFIC REGIONAL SYSTEM TO PROVIDE SERVICES AT A LOWER COST* THAN SYSTEMS COMPRISED OF ONLY TWO ORBITAL POSITIONS -- WHICH IN TURN WILL MAKE CUSTOMERS MIGRATE TO THE TONGASAT SYSTEM -- BECAUSE OF

  - AVAILABILITY OF SIX ORBITAL POSITIONS
  - LOWER SATELLITE COST DUE TO MULTIPLE PROCUREMENT
  - VAST COVERAGE AREA AT HIGH EIRP'S
  - LOWER TARIFFS
  - BETTER ELEVATION ANGLES FOR EXTENSIVE NETWORKS
  - ABILITY TO EMPLOY VERY SMALL TVRO'S
  - MAXIMUM IN-ORBIT SPARING PROTECTION
  - ALTERNATIVE PATH POSSIBILITIES (MANY SATELLITES)
  - AVAILABILITY OF BOTH C- AND Ku-BAND
  - LOWER TRANSPONDER-YEAR UNIT COST
  - HIGHER RELIABILITY AND LONGER LIFE OF LARGER SATELLITES
  - CONVENIENT NEWS FEEDS AND MILITARY USES OF SMALL, TRANSPORTABLE EARTH STATIONS
  - USE OF VSAT EARTH STATIONS WITHOUT "HUBBING"
  - LESS EXPENSIVE INSTALLATION OF EXTENSIVE

TONGASAT "CORE" COVERAGE



130.0E - 142.5E
(RANGE OF 4 ORBITAL POSITIONS)

EACH SATELLITE USES SEVERAL BEAMS WITHIN ITS COVERAGE

High EIRP's

Beam	C-Band	Ku-Band
Japan/China Beam	42.0 dBW	51.7 dBW
Malay Beam	40.9 dBW	50.5 dBW
Southern Beam	37.7 dBW	45.4 dBW
US Beam	41.1 dBW	54.8 dBW
Pacific Beam	38.9 dBW	--

NETWORKS, DUE TO HIGH ELEVATION ANGLES

- *THE SIX TONGASAT SATELLITE ORBITAL POSITIONS WERE CAREFULLY SELECTED* TO ASSURE SUCCESSFUL COORDINATION WITH COUNTRIES HOLDING SATELLITE ORBITAL LOCATIONS IN NEIGHBORING ORBIT LONGITUDES, *WHILE PRESERVING TOTAL GLOBAL COVERAGE AS SEEN FROM EACH SATELLITE AND HIGH POWER LEVELS FOR SMALL EARTH STATIONS* -- THE TONGASAT SATELLITES ARE ALLOWED TO OPERATE AT THE HIGHEST PERMISSIBLE FLUX DENSITY LEVELS, IN ACCORDANCE WITH THE RADIO REGULATIONS. MOST OTHER SATELLITE POSITIONS REGISTERED BY OTHER COUNTRIES IN THE ORBITAL ARC OF INTEREST ARE NOT AUTHORIZED TO OPERATE AT MAXIMUM PERMISSIBLE LEVELS, AND ARE NOT ALLOWED TO ILLUMINATE THE WHOLE EARTH AS SEEN FROM EACH SATELLITE.

- IT IS OF CRUCIAL IMPORTANCE TO RECALL THAT THE TONGASAT ALTERNATIVE PROVIDES *MORE ORBITAL POSITIONS THAN ANY OTHER IN THE ASIA-PACIFIC REGION,* AND THAT THE ORBIT POSITIONS REGISTERED ARE ALREADY IN THE IFRB "COORDINATION" STAGE WITH OTHER COUNTRIES, WITH THE KIND ASSISTANCE OF THE IFRB/ITU IN GENEVA.

- IT IS ALSO OF GREAT IMPORTANCE TO RECOGNIZE THAT THE GOVERNMENT OF THE KINGDOM OF TONGA IS FULLY IN SUPPORT OF THE TONGASAT REGIONAL SYSTEM. THE GOVERNMENT OF THE KINGDOM HAS ISSUED DIPLOMATIC AND OTHER GOVERNMENT-TO-GOVERNMENT INVITATIONS TO OTHER COUNTRIES, INVITING THE OTHER GOVERNMENTS TO ALLOW SIGNATORIES/ENTITIES TO CARRY TRAFFIC IN AND OUT OF THEIR RESPECTIVE COUNTRIES. *NO SATELLITE SYSTEM IS ATTRACTIVE TO CUSTOMERS UNTIL SUCH "LANDING RIGHTS" ARE OBTAINED IN EACH COUNTRY PARTICIPATING IN A NETWORK.*

EXISTING SATELLITE SYSTEMS OVER THE ASIA-PACIFIC AREA ARE NOT IN A POSITION TO PROVIDE THE SAME EXTENSIVE COVERAGE AND INTERCONNECTIVITY AS TONGASAT. THEY HAVE ONLY TWO OR THREE ORBITAL POSITIONS EACH. THE INDONESIAN PALAPA SYSTEM IS TOO FAR WEST IN ORBIT TO BE ABLE TO INTERCONNECT DIRECTLY WITH NORTH AMERICA. THE ASIASAT SATELLITE IS LIKEWISE TOO FAR WEST IN ORBIT. VARIOUS DOMESTIC SYSTEMS MAY NOT EXPAND THEIR COVERAGE AREAS TO PROVIDE REGIONAL SERVICES, DUE TO THEIR INITIAL IFRB AUTHORIZATIONS. IF THEY ATTEMPT TO EXPAND, THEY LIKELY WILL NOT BE ABLE TO COORDINATE SUCCESSFULLY WITH NEIGHBORING SATELLITES.

ASPIRING TO OPERATE SYSTEMS OVER ASIA OR THE PACIFIC ARE PACSTAR AND PANAMSAT. THEY HAVE SATELLITE ORBITAL POSITIONS TOO FAR TO THE EAST AND/OR TOO FAR TO THE WEST TO PROVIDE IDEAL ELEVATION ANGLES FOR THE MAJORITY OF POPULATION CONCENTRATIONS IN EAST ASIA AND AUSTRALASIA, WHERE THE MAJOR POPULATIONS ARE CONCENTRATED. THUS TONGASAT IS THE ONLY ENTRANT WITH POSITIONS IN THE 130.0E - 142.5E LONGITUDE ORBITAL ARC, ESTABLISHING A REGIONAL SYSTEM.

INSTITUTIONAL ARRANGEMENTS

I. REGULATORY ASPECTS

User access to the Tongasat satellite network is of course left for each country to regulate. In particular, for international links, each government can decide which alternative is best for its telecommunications carriers and users: Either the respective governments may wish to permit their users of the Asia-Pacific regional system to have direct access to the satellites from their small customer owned earth stations ... Or each government may wish to permit government owned or franchised communications carrier owned earth stations to be installed on or near customer premises ... Or installed in every community, so that long distance, costly links through the terrestrial networks are not necessary. *To make the maximum economic savings possible for the users, the government may wish to permit direct access to the satellites by such customer premise or community earth stations,* by-passing the existing terrestrial network entirely, especially in rural areas.

It is likewise a matter of course that each government dictate *either that the private sector be allowed to provide a Signatory to the system ownership consortium, the "International Ownership Body (IOB)", or that the Signatory be a Government Agency, or to let the Signatory of another country represent it.* One large telephone company or VAN carrier, or consortiums of carriers or cellular or telephone companies may wish to form a Signatory of one country, while the single national telecommunications provider of another country acts as its Signatory to the IOB. The IOB is an international partnership owned by Investors and Investing Signatories.

Finally, the regulatory body of each nation may wish to impose tariffs, rules or restrictions on the resale by its Signatory of circuits or transponders, to the communications users in that country or its territories. *Tonga and Tongasat urge nations to stimulate as much as possible the establishment of a Signatory to the Tongasat Regional System, for the good of its end-users, by not imposing rules that would unduly limit the net earnings of the Signatory.* Each Signatory will surely make its offerings to end-users as attractive as possible, in order to maximize revenues, since the Signatory will in most cases compete with other providers of international links, via satellite or cable. Likewise, each Signatory will strive to provide various services desired by its subscribers or customers. (The same applies to a great extent to Signatories of INTELSAT, in that their end user tariffs must successfully compete with alternate means.)

REGULATORY & INSTITUTIONAL

- GOVERNMENTS ALLOW USER ACCESS
- BY-PASS LONG LAND-LINES
- COMMUNITY OR CUSTOMER PREMISE EARTH STATIONS
- EACH COUNTRY DESIGNATE SIGNATORY
  - GROUP OF COMMERCIAL CARRIERS
  - GOVERNMENT ENTITY
- GOVERNMENTS REGULATE TARIFFS
- SIGNATORIES TO REGIONAL SYSTEM SET CHARGES TO RETURN 14% - 22%

LEGAL/REGULATORY ASPECTS

- TONGA HAS RIGHT TO USE EACH SATELLITE POSITION PROVIDED SATELLITE LAUNCHED BY 1999 INTO EACH POSITION
- IN ACCORDANCE WITH RADIO REGULATIONS ALL LEGAL MATTERS FINISHED, EXCEPT FOR TECHNICAL COORDINATION WITH OTHER COUNTRIES
- COORDINATION WITH INTELSAT RE ECONOMIC HARM WILL TAKE PLACE AFTER IOB ESTABLISHED
- EACH COUNTRY MAY PERMIT CARRIER ACCESS OR APPOINT SIGNATORY (EXCLUSIVE)
- NO FCC INVOLVEMENT, EXCEPT IN USA

IOB - INTERNATIONAL OWNERSHIP BODY

II. OWNERSHIP AND ORGANIZATION

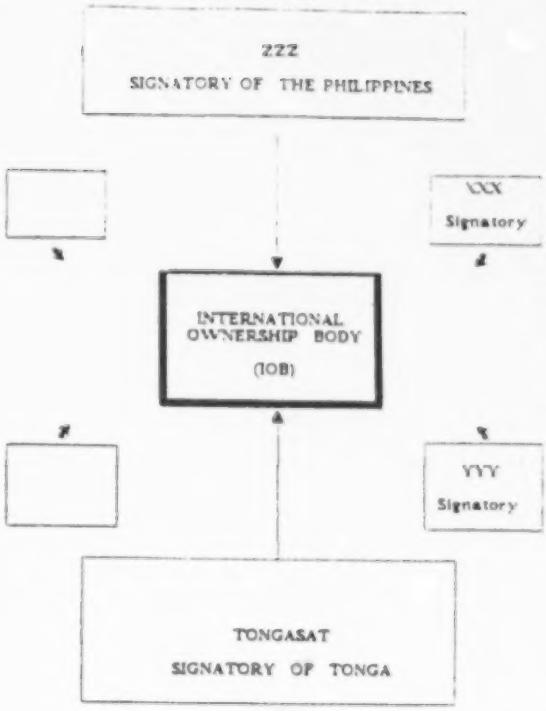
THE IOB WILL BE A TRULY COOPERATIVE INTERNATIONAL PARTNERSHIP. THE FUNCTIONING OF THE IOB IS SOMEWHAT SIMILAR TO THE INTELSAT AND THE EUTELSAT OPERATING AGREEMENTS. IT WILL HAVE A SINGLE TIER STRUCTURE, SINCE NO GOVERNMENT PARTIES NEED BE INVOLVED, ONLY PRIVATE OR GOVERNMENT SIGNATORIES AND INVESTORS/PARTNERS. ALSO, INSTEAD OF THE NECESSITY OF HAVING INVESTING SIGNATORIES REPRESENTING EACH COUNTRY (AS IN INTELSAT), A COUNTRY CAN APPOINT A NON-INVESTING SIGNATORY, OR LET A SIGNATORY OF ANOTHER COUNTRY REPRESENT ITS INTERESTS IN MEETINGS OF THE IOB.

IT IS LIKELY THAT A SMALLER GROUP OF PRIVATE OR GOVERNMENTAL INVESTING ENTITIES, SOME BUT NOT ALL OF WHICH ARE FRANCHISED BY THEIR RESPECTIVE GOVERNMENTS AS INVESTING SIGNATORIES, WILL OWN AND OPERATE THE SYSTEM TOGETHER WITH TONGASAT. NON-INVESTING SIGNATORIES WILL BE ENTITLED TO OBSERVER STATUS ON THE IOB. PARTICIPATING NATIONS' REGULATORY AUTHORITIES OR THEIR SIGNATORIES WILL OF COURSE SET THE TARIFFS CHARGED TO END-USERS IN THEIR RESPECTIVE COUNTRIES.

THIS OWNERSHIP STRUCTURE PROVIDES AN ADVANTAGE TO COUNTRIES HAVING NO INTERESTED INVESTOR. IT PERMITS A SMALLER GROUP OF FINANCIERS FROM SOME OF THE PARTICIPATING COUNTRIES TO EARN A REASONABLE AND ATTRACTIVE RETURN ON INVESTMENT, WHILE EACH AND EVERY PARTICIPATING COUNTRY CAN AVAIL ITS USERS OF THE COMMUNICATIONS SERVICES, *WITHOUT THE NECESSITY OF GOVERNMENTAL OR PRIVATE SECTOR INVESTMENT FROM AN ENTITY IN THAT COUNTRY.* INDIVIDUAL USERS OR CARRIERS OR THE SIGNATORY IN EACH COUNTRY NATURALLY NEED TO FINANCE THEIR EARTH STATIONS AND PAY FOR THE SATELLITE CAPACITY THEY USE.

THUS, NO COUNTRY NEEDS TO BE LEFT OUT BECAUSE OF FINANCIAL CONSIDERATIONS.

TO SUMMARIZE, EACH PARTICIPATING COUNTRY NEEDS ONLY TO LICENSE OR FRANCHISE OR APPOINT A SIGNATORY TO THE IOB, WHETHER AN INVESTING OR NON-INVESTING SIGNATORY, WHICH IS THE CARRIER OF TRAFFIC IN AND OUT OF THAT COUNTRY ON THE TONGASAT REGIONAL SYSTEM. THERE IS NO FINANCIAL COMMITMENT BY THE GOVERNMENT. SIGNATORIES CAN BE COMPOSED OF ANY ENTITIES EACH GOVERNMENT CHOOSES TO PERMIT TO PROVIDE THE DIRECT ACCESS TO THE TONGASAT ASIA-PACIFIC REGIONAL SATELLITES. THEY CAN BE PRIVATE, COMMERCIAL OR GOVERNMENTAL ORGANIZATIONS, AND THEY CAN BE FINANCIER OR USER ENTITIES. A COUNTRY MAY APPOINT AN INVESTOR OR SIGNATORY OF ANOTHER COUNTRY TO REPRESENT IT IN THE IOB, WHILE ALSO LICENSING THAT SIGNATORY, OR FRANCHISING ANOTHER DOMESTIC ENTITY, TO CARRY THE TRAFFIC IN AND OUT OF ITS TERRITORY.



INTERNATIONAL OWNERSHIP BODY (IOB)
FINANCIAL/INSTITUTIONAL ASPECTS

- ANY ENTITY CAN PARTICIPATE IN FINANCING OF IOB TOTAL SYSTEM
- PREFER 5 TO 10 INVESTORS FOR ENTIRE $400 - $600 MILLION IOB SYSTEM – REAP ROI OF 14% - 26%
- EACH COUNTRY MAY APPOINT SIGNATORY
  - EITHER INVESTOR IN IOB
  - OR NON-INVESTING CARRIER'S CARRIER OR GROUP OF CARRIERS
  - OR EACH END USER AUTHORIZED TO DEAL DIRECTLY WITH IOB
  - OR GOVERNMENT ENTITY
- TONGASAT UNDER CONTRACT AS INITIAL SYSTEM MANAGER
- ANY INVESTING SIGNATORY COULD PROVIDE TT&C

FINANCIAL CONSIDERATIONS

The total cost of satellite procurement and launching of the initial Tongasat Regional System is of course dependent on the type and number of satellites selected. The cost range for the first generation of satellites is estimated to be from US$350 million consisting of a 2 satellite system of relatively simple satellites with limited capacity, to about US$600 million or more for a 3 - 4 satellite system of a relatively complex nature. These figures include a TT&C station and insurance.

Earth stations in each country are of course an investment made by either authorized carriers or by each customer or by the Signatory to the "IOB" or Investor of that country.

An initial complement of two medium capacity satellites can be launched for a total cost in orbit of about US$300 million. In any case, follow-on satellites will probably be more complex or heavy, with hybrid C- and Ku-band high power transponder payloads, to satisfy the growing demand for capacity during the next century.

It is therefore the aim of the Government of Tonga and Tongasat to work together with all nations willing to franchise an entity to participate, in order to take advantage of the economy of scale, so necessary to finance and make commercially attractive a regional satellite system. The IOB will be an international partnership of Signatories and Investors, exercising maximum corporate type of efficiency, resulting in lowest costs for all.

Investors of the IOB can expect an annual Return On Investment (ROI) in the 14% - 22% range. *Most Signatories will of course earn far more on the re-sale to carriers or end-users of the capacity the Signatories purchase at whole sale prices from the IOB.* That is, for example, how the Signatories of INTELSAT experience very good revenues and net earnings.

Typical private Investors in the IOB Regional System may include authorized communications providers, telephone companies, television and radio networks/broadcasters, cultural and educational television providers, government franchised communications carriers, carriers' carriers, satellite manufacturers, earth station and launch vehicle manufacturers, banks, venture capitalists, multi-national and trading companies, value added networks (VANS), cable TV system operators, discount telephone carriers, etc.

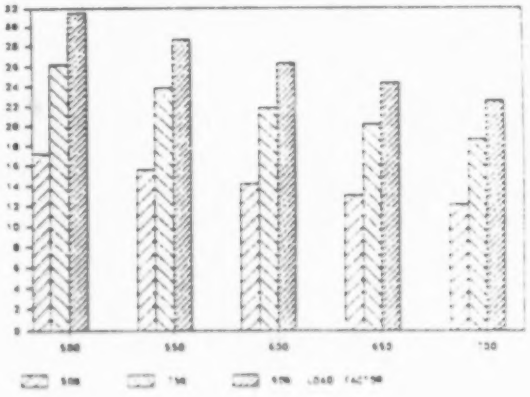
The TT&C station can be located in any country that is represented by a significant Investor or Investing Signatory, subject to approval of all then current Investing Signatories and Investors which are not Signatories.

TYPICAL FINANCIERS

- COMMUNICATIONS CARRIERS
- TELEPHONE COMPANIES
- TV & RADIO NETWORKS
- PT & T
- MULTI - NATIONAL COMPANIES
- BANKS, FINANCIAL INSTITUTIONS
- MANUFACTURERS OF SATELLITES, LAUNCH VEHICLES AND EARTH STATIONS
- TV CABLE NETWORKS

RETURN ON INVESTMENT OF INTERNATIONAL OWNERSHIP BODY

3 C/KU-BAND SATELLITES



ANNUAL ROI VS TOTAL INVESTMENT IN US$ MILLIONS
FOR LOAD FACTORS OF 50% 75% AND 90%

CONCLUSIONS

THE KINGDOM OF TONGA AND TONGASAT INVITE AND URGE INTERESTED END-USERS, TELEPHONE COMPANIES, CELLULAR TELEPHONE OPERATORS, VALUE ADDED NETWORKS, TV AND RADIO BROADCASTERS, COMMERCIAL CARRIERS AND OTHER TELECOMMUNICATIONS FACILITY PROVIDERS TO EXPRESS THEIR VIEWS CONCERNING PARTICIPATION OF THEIR USERS AND SUBSCRIBERS IN THE FORM OF FRANCHISING AN ENTITY TO CARRY TRAFFIC IN AND OUT OF THEIR COUNTRY. WE APPEAL TO INTERESTED PARTIES TO OBTAIN SUCH PERMISSION THROUGH THEIR APPROPRIATE GOVERNMENT INSTANCES. NO NATION CAN AFFORD TO BE LEFT OUT.

TONGA AND TONGASAT INTEND THAT THE ASIA-PACIFIC REGIONAL SYSTEM BE COMPLEMENTARY TO THE INTELSAT SYSTEM AND THAT IT BENEFIT ALL USERS IN THE ENTIRE REGION OF ASIA-PACIFIC, BY PROVIDING COST-EFFECTIVE RURAL AND INTER-ISLAND DOMESTIC AND INTERNATIONAL LINKS AS WELL AS LOW-COST EDUCATIONAL, CULTURAL, ENTERTAINMENT AND RELIGIOUS TV PROGRAM DISTRIBUTION, FOR THE BENEFIT OF ALL.

MANY COUNTRIES IN THE ASIA-PACIFIC REGION MAY AGREE WITH THE KINGDOM OF TONGA THAT A REGIONAL SATELLITE COMMUNICATIONS SYSTEM CAN PROVIDE SEVERAL KINDS OF SERVICES OF POTENTIALLY GREAT BENEFIT TO INDUSTRY, TRADE AND TOURISM OF THE REGION. IT IS OFTEN BENEFICIAL IN TELECOMMUNICATIONS TO HAVE AVAILABLE ALTERNATIVE FACILITIES, TO ASSURE COST-EFFECTIVE SERVICE ADVANTAGES AND TO OFFER USERS IN EACH COUNTRY A CHOICE OF TELECOMMUNICATIONS CARRIERS. IN OTHER WORDS, COMPETITION GENERALLY BENEFITS THE USERS OF COMMUNICATIONS SERVICES.

THERE ARE PRECEDENTS OF REGIONAL SATELLITE SYSTEMS ESTABLISHED OUTSIDE OF INTELSAT, MOST NOTABLY EUTELSAT, INTERSPUTNIK, ARABSAT, THE INDONESIAN PALAPA SYSTEM AND PANAMSAT. OTHERS ARE IN THE MAKING, SUCH AS ONE SYSTEM IN AFRICA AND VARIOUS ATLANTIC OCEAN REGIONAL SYSTEMS. OF COURSE, "COORDINATION" WITH INTELSAT CONCERNING ARTICLE XIV(D) "SIGNIFICANT ECONOMIC HARM" MAY AT SOME POINT BE NECESSARY BY COUNTRIES AND TERRITORIES OR JURISDICTIONS THAT BELONG TO INTELSAT. HOWEVER, SUCH COORDINATION WITH INTELSAT CAN TAKE PLACE LONG AFTER THE IOB IS FORMED AND NEED ONLY BE UNDERTAKEN IF THE TONGASAT REGIONAL SYSTEM EXCEEDS CERTAIN THRESHOLD LIMITS OF COMMUNICATIONS CAPACITY USED FOR INTERNATIONAL COMMUNICATIONS AND PUBLIC SWITCHED TELEPHONE NETWORK SERVICES, AS ADOPTED BY A RECENT INTELSAT ASSEMBLY OF PARTIES. IT IS POSSIBLE THAT THE ENTIRE FIRST GENERATION OF SATELLITES OF THE TONGASAT REGIONAL SYSTEM MAY OPERATE WITHIN THOSE THRESHOLD LIMITS, SO THAT INTELSAT COORDINATION IS NOT NECESSARY FOR A LONG TIME, MORE LIKELY NOT UNTIL THE LATE 1990'S.

WE WOULD BE GRATEFUL TO KNOW WHICH INSTANCES OF YOUR GOVERNMENT OR WHICH SEGMENTS OF YOUR PRIVATE SECTOR INDUSTRY AND FINANCIAL COMMUNITY AND COMMUNICATIONS USERS MAY WISH TO DISCUSS THIS INVITATION WITH US FURTHER.

442

THANK YOU VERY MUCH FOR YOUR KIND ATTENTION!

TONGASAT'S VSAT SYSTEM

- REACHES DIRECTLY FROM ONE REMOTE VSAT TO ANOTHER (ON PALAPA MUST "HUB")
- C-BAND 1.8 METER DIAMETER
  Ku-BAND 1.2 METER VSAT DIRECT VOICE AND DATA
- CELLULAR SYSTEMS IN REMOTE AREAS OF ONE COUNTRY CAN INTERCONNECT DIRECTLY TO RURAL OR ISLAND TELEPHONE COMPANIES IN OTHER COUNTRIES

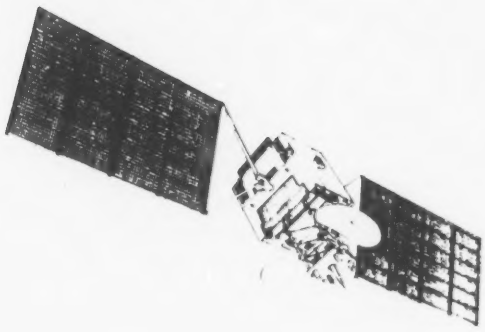
CONTACT NAMES AND ADDRESSES



WE INVITE YOUR COMMENTS.

FRIENDLY ISLANDS SATELLITE COMMUNICATIONS, LTD. (TONGASAT) IS A PRIVATE TONGAN COMPANY. IT IS THE EXCLUSIVE AGENT OF THE KINGDOM OF TONGA FOR DEALING WITH AND MAKING ARRANGEMENTS FOR ORGANIZATIONS TO LAUNCH INTO AND/OR OPERATE ONE OR MORE SATELLITES IN ORBITAL POSITIONS REGISTERED WITH THE IFRB ON BEHALF OF TONGA. AS SUCH, TONGASAT HAS REGISTERED ITS SATELLITE POSITIONS THROUGH THE GOVERNMENT OF THE KINGDOM OF TONGA.

PLEASE RECOMMEND TO INTERESTED USER GROUPS OR OTHER INTERESTED PARTIES AND COMMERCIAL ORGANIZATIONS IN YOUR COUNTRY TO CORRESPOND WITH ANY QUESTIONS TO TONGASAT:

DR. MATS C. NILSON, MANAGING DIRECTOR
TONGASAT

MANILA OFFICE FAX 63-2 817-6112
SAN DIEGO OFFICE FAX 1-619-270-4652
NUKU'ALOFA OFFICE FAX 676-22915

OR TO THE GOVERNMENT OF THE KINGDOM OF TONGA:

MR. SIONE KITE, DEPUTY CHIEF SECRETARY AND
DEPUTY SECRETARY TO CABINET
OFFICE OF THE PRIME MINISTER
NUKU'ALOFA, KINGDOM OF TONGA

FAX 676-23888

WE WOULD BE PLEASED TO HAVE YOUR RECOMMENDATIONS AND SUGGESTIONS IN WRITING.

YOUR CONTRIBUTIONS WILL ASSIST US IN DETERMINING WHICH SATELLITE ORBITAL POSITIONS ARE OF GREATEST INTEREST FOR THE INITIAL SATELLITE LAUNCHES TO BE RESPONSIVE TO DEMAND.

TONGASAT

An ISDN Multimedia Distance Learning Trial: Phase One Results Report

Professor Terry Curtis - California State University, Chico
Dr. Janet Davidson - Pacific Bell
Ms. Joyce Inkrott - AT&T Network Systems
Mr. John Perley - AT&T Network Systems

1. ABSTRACT

This is a report on a developmental test of a multimedia distance learning platform capable of supporting interactive video, voice, data, and graphics using BRI ISDN lines for transmission.

PROJECT OVERVIEW AND OBJECTIVE

The general objective of the Multimedia Distance Learning project was the development and assessment of an Integrated Services Digital Network (ISDN) Conferencing System as a potential solution to the national shortage of qualified science and math teachers.

The motive for action was based on the perceived decline in education services and resources in the United States. Noted education expert Arthur Melmed's February 1987 report to the National Science Foundation clearly identified the lack of capability and capacity as follows: "The current state of our schools is that there is a lack of adequate teacher personnel in exactly the areas where productivity must rise. Fewer than half of the teachers of precollege math and science are certified in all the subjects they teach. Of the 14,000 to 15,000 high schools in the U.S., 7,100 have no physics courses, 4,200 have no chemistry courses and 1,900 no biology. In addition, many courses lack fundamental rigor because of inadequate teacher capability."

Recognizing the need for improvement in education delivery, Pacific Bell and AT&T are partnering with California State University in Chico, a national leader in satellite and microwave distance learning technologies, to assess the use of ISDN networks for teaching.

A premise shared by the project sponsors was that an ISDN distance learning network would be more cost-effective than private leased line facilities or satellite, and would also provide sufficient bandwidth to support the use of voice, data, video and graphics for improved interaction between teachers and students. This premise was also supported by a number of industry experts who predicted that the integration of the telephone, TV, and computer could potentially revolutionize traditional approaches to education and entertainment.

Since theories need to be supported by facts before business decisions can be made, Pacific Bell, AT&T Network Systems and California State University Chico agreed to jointly assess the feasibility of the concept. A number of project hurdles such as system design, instruction module development, team participation, etc. needed to be crossed in order to proceed. Recognizing the complexity of the tasks, a three phase project plan was conceived. Each phase was designed to progress in functionality from point to point voice, data and video conferencing to fully interactive multimedia multipoint distance learning.

This report documents the findings of Phase One as a foundation for future phases. It is assumed that additional objectives will be identified and addressed by the respective teams upon review of this report.

PHASE ONE DESCRIPTION

Phase One focused on the development and test of a single site delivery of a multimedia class in Physics. Equipment (hardware and software) was installed prior to conducting the class modules in order to minimize the "Hawthorne Effect". The classes were delivered in May 1991, and recorded in VHS videotape for evaluation and review.

Fairview High School, a continuation school in Chico for returning students, was selected as the initial test site. The team members felt that Fairview provided an extremely demanding test environment because it's demographics represent a mix of at risk, economically, socially and academically disenfranchised students. Mr. Van Veen, the science teacher at Fairview, also has a reputation for education innovation and is an active member of the California State Education

Department's Mathematics Curriculum Committee. The team believed that the successful testing of the ISDN BRI model with this particular population would demonstrate ease of use for all learners.

The overall goals of the project were quite ambitious. Early meetings with the project team indicated that an ideal distance learning environment would be technically possible but economically prohibitive. A set of ideas and concerns were derived from interviews with four experienced instructors. The interviewees were: Dr. Joseph Lipson, Dr. Terry Curtis, Dr. John Ittelson and Mr. John Van Veen. A summary of their perspectives follows.

- Instructors want real-time full-duplex audio to support classroom interaction.
- Minimal equipment should be required at a remote site in light of the limited financial resources, and because fewer devices would mean easier setup, operation, security, and maintenance.
- The need for two way interactive video was not seen as a key initial concern. This subject will be explored during the trial.
- Instructors want a database of modern visual aids to supplement their lectures, e.g. videodisc access.

The **OVERALL PROJECT TEAM** was chaired by Dr. Terry Curtis. Also, in response to the intricacy of the project, three teams were created along task lines in order to ensure maximum objective coverage. A description of these teams follows:

The **INSTRUCTIONAL DESIGN TEAM** was charged with developing a physical science class module which would rely heavily on visual reinforcement, and required a "MASTER TEACHER". Team members were Dr. Joseph Lipson, Mr. John Van Veen, Dr. John Ittelson and his students.

The **TECHNOLOGY PLATFORM TEAM** concentrated on the development of a multitasking multimedia platform that would allow access to an ISDN equipped central office and support the effective transmission of multimedia PC based instructional modules. Team members were Ms. Joyce Inkrott, Mr. John Mitchell, Mr. Tom Leslie, Mr. Charles Eyster, Dr. John Ittelson and a number of his students.

The **EVALUATION AND DOCUMENTATION TEAM** had the charter of providing objective information that would assist decision makers during the progressive stages of the project program development and implementation. The members of this team are Dr. Janet Davidson and Mr. John Perley. Dr. Robert Main and his support team at CSUC plan to issue an independent evaluation of the learning impact of the technology. Dr. Main's assessment will provide "empirical evidence of the learning outcomes and documentation of the instructional methods, delivery techniques and system requirements to assist educators, curriculum developers and instructional technologists in making decisions on the adoption of similar learning projects".

PHASE ONE TEST RESULTS

Four one-hour classes were taught, using the ISDN network and platform, on May 21, 23, 28 and 30th. The head end, or teacher workstation, was located at the CSUC library and operated by Mr. Van Veen. The remote end, or student workstation, was set up in Mr. Van Veen's class room at Fairview High School. The class sessions included teacher lecture, real-time interactive two way audio and video communication, laserdisc video clip display, image transfer and screen annotation, all controlled from the teacher workstation. Students were also able to annotate and send graphics, images or text.

Pre-class interviews were conducted with the team members in order to get a sense of concern and personal desires regarding the exercise. Post-class interviews were conducted to evaluate actual versus expected results.

Mr. Van Veen's pre-class impressions included: A great amount of pre-class "free floating anxiety" because this was the first lesson in an unknown environment. The preparation of the class session would lead to a "superior lesson" because previously unavailable media resources are now available.

Mr. Van Veen's post class impressions included: "TERRIFIC CLASS". The students were super and they contributed to the success of the session.

Familiarity with the equipment led to successful class delivery. Volume of available material exceeded student capacity and needs to be adjusted in subsequent classes. Interaction was excellent. Mr. Van Veen commented that "before today's class I did not see a real need for two way video. Today I do." The system as it stands now is great. Some additional enhancements such as private conferencing, a wider field of view and slide/visual out of sequence selection would be helpful. Concerns about keystroke patterns and the potential for disrupting a class session by inadvertent keystrokes indicated that a click and select icon command would be more user friendly.

The post class interview with the students indicated that they felt the class was successful. Mr. Van Veen's teaching style contributed to the success. They felt that they got as much out of the delivered course as if Mr. Van Veen was physically present in the classroom. The recording of the experiment and the presence of the project observation team was not disruptive. They felt that Mr. Van Veen conducted the class well and they did not see the need for an on-site instructor.

On the whole, the project team was pleased with the outcomes of the Phase One experiment as a precursor for the following phase.

CONCLUSION AND COMMENT

This report covers interim results of a project in process of completion. The conclusions presented here must be considered preliminary and are subject to change as the project progresses.

Given that the objective of Phase One was to provide the project team with a determination of design factors and base requirements for subsequent phases, the experiment has been a success. The evaluation of the effectiveness from the student and teacher perspective is that the remote module delivery is as effective as an on site delivery method. From that viewpoint, the team is encouraged to test the simultaneous delivery to multiple class sites.

Please note that the Phase One student population is classified as an "at risk" universe. Therefore we believe that their impressions are not directly transferable to a "mainstream" mass market environment. The indication from instructors familiar with the Phase One students' normal class activities indicated that normal attention to instruction was experienced throughout the experimental classes.

A key design question for the technology team was whether the difference in the quality of real-time video at 64 KBPS or 128 KBPS would be apparent to the students. The video tape record indicates, by lack of comment, that the variation in bandwidth was transparent to the class participants.

Our review of the class sessions and commentary suggests that the following items be addressed in future phases:

- The mechanisms and procedures for the video tape recording of the class sessions and other project activities needs to be strengthened. A number of Phase One video records were unusable because of poor audio quality. In addition, fixed angle shots of the classroom did not allow for a review of participants' physical reactions (body language) to the delivery method and course materials.

- The need for a wider field of view from the teacher workstation was voiced by Mr. Van Veen.

- The ability for remote camera panning of the class site would enhance the instructor's ability to monitor the class activities. Remote panning will also minimize the need for students to parade their work before the classroom cameras.

- Easier access to locally stored multimedia materials on an ad hoc basis. Mr. Van Veen's request for icon control, rather than function key control, is being addressed.

- Improvement in the audio quality and associated mechanisms

- Student and Teacher operational training procedures need to be improved. A review of the tapes showed that the participants, both teacher and students, had occasional difficulty with the operation of the equipment. Some thought should be given to the development of equipment operation training as well as the design of a more friendly user interface.

- Automation of the "Private Conference Feature" would allow the instructor to conduct a private conference with a student without disrupting the class flow.

- The impact of end user interface when the experiment is conducted among multiple parties needs to be assessed. This assessment could be conducted within the context of a proposed Pacific Bell/AT&T Network Systems Joint Market Research project.

- Regarding the evaluation of effectiveness, we feel that the control measures included in Phase One were adequate for the stated purpose of Phase One. However, in line with Dr. Main's Evaluation Plan and the CSUC Distance Learning Grant Application, conscientious adherence to the proposed measurement methodology is essential if inferences are to be made regarding the impact of this technology on learning.

- Students enjoyed the use of laserdisc video and animated graphics. These elements contributed to the acceptance of the class. The preparation of class modules which incorporate laserdisc videos and pre-class prepared graphics requires a substantial amount of effort on the part of the instructor. We recommend that future phases include the testing of technology without these elements. The conducting of a class with only ad hoc elements such as a scanner, electronic tablet, interactive voice and video, and screen sharing will indicate the utility of the system for those classes which are not enhanced by laser disc video or animated graphics.

- Future measure of effectiveness should include comparisons with a control class as a benchmark. This would provide for a qualitative comparison of learning outcomes from different instructional approaches. An evaluation of the effectiveness of the multimedia method is a key element for encouraging future development efforts.

- Fairview High School provided an acceptable test site. However, if this teaching approach is to be evaluated for the mass education market, the inclusion of traditional high schools in later phases is required. The incorporation of additional schools with larger class populations and different instructors would provide the Evaluation Team with a means of assessing the effectiveness and utility of the multimedia distance learning application as a mass market offering.

In conclusion, the following findings from Phase One are key elements in planning future phases:

- The technology worked according to expectation.

- The point to point ISDN connectivity performed as required.

- The teacher interface performed adequately.

- The students accepted the concept and performed at normal levels without the in-room presence of a qualified science teacher.

DISTANCE LEARNING SYSTEM USING ISDN

Gengo Tazaki
Fujitsu International Engineering Ltd

Ngee Ann Polytechnic
Singapore

ABSTRACT

This paper describes a field trial in distance learning using ISDN public network in Singapore. Computer-Based Training (CBT) is adopted as the delivery system as it can be efficiently administered at low cost. The CBT system adopted will be able to develop and deliver courseware in English, Spanish, Japanese and Chinese. Fujitsu Limited/Japan and Fujitsu (Singapore) Private Limited conducted an experimentation in Singapore using IBM PC compatible (with EGA/VGA) and the FETEX-150 digital switching system. A collaboration programme between Fujitsu/ Singapore and the Ngee Ann Polytechnic of Singapore was launched in 1991 to develop and implement a full scale ISDN distance learning system for the campus by 1993. The joint development project could also be applied throughout the Asia Pacific region and many other regions in the future.

INTRODUCTION

The Singapore Telecom has introduced ISDN public network in the country. Many sectors of industry are encouraged to explore the application of ISDN. In the education industry, the transfer of instructional materials with voices over distances is the target of development. The idea of ISDN distance learning is thus formalized **[*1]**.

The exploitation of the computer technology and telecommunication know-how results in the emergence of ISDN distance learning as a new challenge to facilitate self-paced learning without the constraints of space, time and instructor. It falls in line with the recent announcement by the Singapore Government to implement distance learning as an avenue for working adults to pursue higher education at home in the evening.

The Ngee Ann Polytechnic of Singapore has, since 1980, placed an importance in the development of computer education to improve the quality of learning and teaching. CBT has been adopted as a delivery system to assist the students who are weak in their studies **[*2]**. In addition, CBT allows students to gain access for an on-line self assessment to determine their level of achievement. These CBT activities form a good platform for distance learning.

Fujitsu which emphasizes on a full exploration of the latest technology for educational use conducted an experimentation to adopt CBT as a delivery system for distance learning using the ISDN public network. The success of the proto-type system leads to the collaboration with Ngee Ann Polytechnic to further research and develop a full scale ISDN distance learning environment. It is believed that the joint project is the first in the Asia Pacific region.

PRESENT SITUATION AND PROBLEM WITH DISTANCE LEARNING

The concept of distance learning is not new. However, efficient mode of delivering information and instructional materials is the main concern. Intense competition for the best possible delivery of information in the shortest time is the norm of today. There is the crucial need to obtain information fast without the constraints of time and location. Conventional distance learning systems can be classified into text-based CAI delivery system with personal computers connected to low-speed public telephone lines via modem. There is also the remote classroom system in which training is administered over satellite TV conference system. Although modem hooking are economical, text-based materials tend to be dull and less interactive. On the other hand, the training delivered through TV conferencing is interesting and highly interactive but the running cost is high.

An alternative solution is sought. Fujitsu/Japan and Fujitsu/Singapore set up a proto-type system to illustrate the use of ISDN public network in Singapore as a means to provide CBT courseware delivery at a low cost. Details of the field trials are reported in the following sections.

ISDN DISTANCE LEARNING FIELD TRIAL

The field trial requires the production of a graphic-intense CBT courseware to be delivered through ISDN public lines at a high speed. The courseware was produced on SchoolBox II which is an integrated authoring system developed by Fujitsu International Engineering Ltd, Japan. The hardware used in the experimentation comprise of IBM PC compatible (with EGA/VGA) and Fujitsu's FETEX-150 digital switching system. The transfer of courseware was on the ISDN B-channel (64 kbps, circuit switched) using a low cost ISDN-PC board which is plugged into the computer. The ISDN-PC board is developed by Singapore Telecom and ITI, a subsidiary company of the Singapore National Computer Board.

The experimentation was satisfactory and considered as sound. Some features of the distance learning system includes :-

a) Educationally sound courseware with appealing colour graphics are offered to anyone at anytime in anywhere. At 64 kbps, a 30 minute learning module can be downloaded in less than 2 minutes. The ISDN line is then immediately disconnected once the module is downloaded. While the module is downloading, an overview is displayed on the screen so that the learners need little waiting time; and

b) Learning records are collected in real time. Records are quickly analyzed so that learners are kept informed instantaneously. The learner information is also put on a database so that individual training problem and the learner's performance can be both addressed. Using the other B-channel, oral instruction can be offered while the learner is viewing his/her lessons on the screen.

It was convinced from the experimentation that the implementation of distance learning system over ISDN network would be able to provide high personalized coaching on non-programmed information to the learners. This is illustrated in Figure 1.

FUJITSU - NGEE ANN POLYTECHNIC COLLABORATION PROGRAMME

With the success of the proto-typing system, Fujitsu prepares to work with academic institution to develop and implement a full scale ISDN distance learning. Fujitsu and Ngee Ann Polytechnic (NP) had an earlier partnership in the development of a CBT Courseware Development Methodology and generic graphics library using Fujitsu's integrated authoring system, the SchoolBox II. The joint project has given the confidence and provided the platform for the two organizations to launch a second collaboration programme on distance learning.

Fujitsu and NP signed a Memorandum of Understanding in 1991 to jointly work on the realization of a full scale development and implementation of ISDN distance learning over the next two years. SchoolBox II will be adopted as the authoring system for CBT courseware delivery. NP builds a common database of courseware and graphics screen library to prepare for the distance learning. Fujitsu assists NP in the technical area of telecommunication.

The scenario of implementing ISDN distance learning are as follows :-

(a) Students residing in or outside the campus retrieve information and instructional materials for learning and upload completed assignments back to the host computer in NP. Students belong to the same working group interact with their tutors at the same time through voice conferencing;

(b) Working adults and NP graduates register for modular courses to further enhance their study at home; and

(c) CBT courseware will be delivered in multiple languages, viz English, Spanish, Japanese and Chinese.

The rationales behind the development of distance learning in NP are based on : -

(a) a large enrolment of 12,700 full time student;
(b) the philosophy of keeping abreast with changing technologies;
(c) more that 40% of NP students own a PC at home;
(d) PC loan/rental scheme to assist students to own a PC; and
(e) many faculties are interested to product CBT courseware.
(f) validation of the effectiveness of CBT as a consistent and efficient delivery system **[*3].**

The ISDN distance learning plans are depicted in Figures 2a - 2b. The plans are to develop a decentralized distance learning environment in which each academic department has its own host computer to serve the students registered under the department, update relevant learner's performance and history record.

Fujitsu and NP development team has begun to research, develop and implement ISDN distance learning system to serve many clusters of students. Each cluster of 25 students will access a course module at the same time. The development schedule over the next two years is shown in Figure 3.

EFFECTS AND IMPLICATION ON THE EDUCATIONAL PROCESS

Education is a vital component of the human development. It is imperative to place a high premium on education to ensure the fullest development of the generation. The investment in distance learning using ISDN public network meets the educational aims of nurturing inquiring minds and developing individual potential to the fullest. Distance learning without the constraints of time, space and teacher provides great opportunities for one to upgrade the skills, broaden knowledge, interact with each other and communicate effectively.

ISDN distance learning has a definite impact on the existing educational process. It is a good means to supplement the traditional instructor-led classroom learning and teaching process **[*4]**. It also serves the aspiration of working adults who wish to enhance their educational level but are unable to follow the conventional full time educational system.

The conventional modes of distance learning are giving ways for the more productive but low cost mode of CBT courseware delivery using ISDN public network. The anticipated lower charges in ISDN line in the near future is an added value to the distance learning development.

In Singapore, the government-led drive to exploit the use of information technology has given a push for the education industry to review, revise and improve upon the educational processes to bring the best in each learner. ISDN distance learning is information technology in education and its widespread application and adoption are anticipated.

The development of ISDN distance learning in Ngee Ann Polytechnic becomes a model of new educational technology. To achieve a wider application of distance learning, the development procedure should be shared among academic institutions and industries involving in training not only in the country but also in many other regions.

CONCLUSION

The realization of ISDN distance learning is a combined effort of Fujitsu and Ngee Ann Polytechnic. It is a manifestation of industrial and academic collaboration **[*5]** to explore and exploit the latest technology for educational use and the benefits of mankind.

1. ABSTRACT

This paper describes an experiment to facilitate electronic communication capabilities among libraries and archives on remote islands in Micronesia in an effort to establish a regional library and information resource sharing network. It also reviews the implementation problems encountered and the benefits derived from this experimental remote electronic mailbox network.

2. INTRODUCTION

Traditionally, in many developed countries, libraries and archives were established to collect and house materials capable of meeting the information needs of their users. With the worldwide information explosion now occurring, individual libraries can no longer collect all the resources necessary to consider themselves self-sufficient. To remedy this, elaborate networks to share information resources have been established throughout the world.

In contrast, libraries and archives in most parts of Micronesia are just beginning to be established, most collections that do exist are severely limited and there are no resource sharing networks in place within the region. Moreover, until the creation and first meeting of the Pacific Association of Libraries and Archives (PIALA) in 1991, there was no formal regional association to even address the issues of developing regional cooperative efforts for resource sharing (1).

The challenge of collecting and sharing information resources in Micronesia is further exacerbated by the remoteness and isolation of the individual islands. Yet, if this region is to continue developing educationally, economically and politically, the establishment of cooperative networks for the sharing of library materials and information resources is critical. The authors feel the key to establishing and maintaining a regional cooperative network for resource sharing is to develop an inexpensive, reliable and effective electronic communication network through an existing appropriate technology analog network.

3. BACKGROUND

Electronic telecommunication among libraries for resource sharing has been effectively utilized throughout the developed world. The literature on this subject cites examples of libraries using electronic mail systems for interlibrary loan of materials as early as 1982 (2). The need for this capability within Micronesia was the basis of the experimental project described in this paper.

In 1991, the Office of Territorial and International Affairs of the United States Department of the Interior funded a project to purchase, install and demonstrate an electronic mail system linking four sites in Micronesia to facilitate interlibrary resource sharing. This experimental system links together the R.F. Kennedy Memorial Library of the University of Guam, and the Palau Division of Archives, the Micronesian Occupational College and the Palau Public Library in Koror, Palau.

This electronic communications link was demonstrated in the Fall of 1991 at the first regional meeting of PIALA held in Koror, Palau. The communications link is based on a specialized modem/electronic mail package designed by Mallard Concepts, Ltd., London, England. The package was originally funded by UNESCO and designed for remote computer networking in Africa and other digitally deprived developing areas. In this

paper, this modem/electronic mail package will be referred to as the Mallard mailbox (3).

In the recent past, commercial voice and facsimile (FAX) transmission capabilities within Micronesia did not exist; or if they did, they were too costly and/or not reliable enough to allow for the development of dependable communication networks. In the early 80's, MICRONET, a subset of the PEACESAT network, began experimenting with computer/voice-integrated networking incorporating modified APPLE 300 baud modems through the PEACESAT ATS-1 satellite. More recently, MICRONET is experimenting with packet terminal node controllers at some of its sites over high frequency (HF) and very high frequency (VHF) radio links.

Now, with the reestablishment of the PEACESAT network utilizing a relocated GOES satellite and the associated earth stations located throughout Micronesia, there is the potential to provide cost effective and reliable message transfer systems. In the experiment described, the newly established PEACESAT nodes provide the conduit for electronic networking among libraries and archives.

4. IMPLEMENTATION

In general, the Mallard mailbox can network remote local libraries and archives into the district or state educational PEACESAT earth station either through the local island telephone loop; or, if applicable and with some hardware modifications, using simplex VHF or HF radio. The messages are then uplinked and received by other similarly linked Pacific Island libraries and archives.

The current Palau intra-island network topology has Mallard mailboxes in the local library and archive offices connected to the local island telephone loop. These on-island sites can leave or pickup messages to or from any other on-island Mallard mailboxes. With this technology, a computer need not be dedicated; the Mallard mailbox only needs to be connected to a phone line to receive or store messages. Periodically, users check the front panel *message-received* indicating lights to determine if there are any received incoming messages.

To facilitate the inter-island networking between distant sites in Palau and the University of Guam, the Mallard mailboxes have been directly connected over the PEACESAT network link. To date, however, the results have been less then reliable. Experimental attenuators have been installed and system levels will be optimized for Mallard mailbox to Mallard mailbox inter-island networking.

At this point, the authors of this paper hope to work directly with the Mallard mailbox designer, Martin Allard, at this PTC' 92 conference.

Currently, the Palau and University of Guam PEACESAT earth stations have Mallard mailboxes on-line to pick up local messages which are then captured and passed over the PEACESAT Telebit T2500L built-in modem at the earth station.

As noted, this experiment was designed to directly or indirectly link remote Micronesian libraries and archives through their local PEACESAT network nodes. However, another data transfer network configuration, known as the star hub topology, is currently being used with the Mallard mailboxes in this project while development work is being done to implement the original design.

The star hub topology works by having remote Mallard mailboxes pass a message to the local PEACESAT earth station's Mallard mailbox. The local earth station operator then transfers data from the earth station's Mallard mailbox on to the Telebit modem which connects and passes the message to the Honolulu PEACESAT hub. The message is then picked up by the destination island's PEACESAT earth station's Telebit modem where it is then operator downloaded to the earth station's Mallard mailbox and finally passed on to the end user's local Mallard mailbox. This provides "BBS" style (store and forward) messaging service to Honolulu and other interested PEACESAT nodes.

5. BENEFITS

The Mallard mailboxes provide for a low-cost private electronic mail network without the need of a dedicated on-line CPU, except when uploading or downloading messages. Any MS-DOS or MacIntosh CPU can upload messages to or download messages from the local Mallard mailboxes.

The system is quick to learn and easy to use, as was shown during the PIALA meeting demonstration referred to previously in this paper. Librarians and archivists attending the demonstration were able to send and receive messages within a few minutes of viewing the demonstration.

The authors of this paper have had excellent communication with the designer of the Mallard mailbox. This is a critical factor when experimenting with new technology in remote areas.

6. FUTURE DIRECTIONS

The Mallard mailboxes installed and demonstrated for this project have become

a permanent electronic link between the four sites. By adding additional Mallard mailboxes, this working system can be expanded to link other libraries and archives in Micronesia and to serve as the foundation for the development of a regional remote electronic communications network, in conjunction with the PEACESAT network.

Reestablishing the PEACESAT network also provides for the regional development and expansion of distance education offerings throughout the Western Pacific (4). The success of distance education course offerings is in no small way dependent on access to information and library resources. This was recognized by the Agricultural Development in the American Pacific (ADAP) Distance Education Consortium; a Library Resources Consultant was included in the membership of the Consortium from its inception (5). Much of the work of this consultant will be in establishing communications capabilities among providers and receivers of distance education courses to meet their library and information needs. The development of the regional library electronic communications network is essential in providing for ADAP's needs.

At present, the PEACESAT earth stations are routinely passing FAX, lumaphone (picture) and data via the Mallard mailboxes and Telebit modems. The authors of this paper will continue to experiment with direct modem to modem connects via the Mallard mailboxes. Work will also continue with the Mallard mailbox designer to develop a standard modem mode to allow networking with other modems and local area networks.

Hopefully, our pioneering efforts will allow for the expansion of the library electronic communications network and will subsequently be used to create other private electronic communications networks throughout the islands covered by the footprint of the PEACESAT-GOES satellite.

Distance Research: Library Research Without Going to the Library

Ralf Neufang
University of Hawaii-Manoa
Honolulu, Hawaii USA

1. ABSTRACT

Appropriate access to research materials has long been dearly missed not only as an essential component of distance education, but by all students and scholars without a research library across the street. In recent years, libraries have begun more and more to take advantage of developments in telecommunications and electronic information storage and retrieval, and it is increasingly more possible to do library research and to obtain library materials without ever having to step into a library building. This paper discusses CD-ROM databases, library online public access catalogs (OPACs) and databases on OPACs, online databases and resources on the Internet.

2. INTRODUCTION

Imagine: library catalogs, journal indexes, full-text document delivery, including graphs, charts and illustrations, the multi-object desktop with text, pictures, sound and video -- all available to you in your office, at home, anywhere -- instantly. This is the kind of scenario that makes the heart beat faster in every information society enthusiast and in many a university scholar.

"All information in all places at all times," proclaim Godfrey and Parkhill in their book Gutenberg Two, and continue, "The impossible ideal. But the marriage of computers with existing communications-links will take us far closer to that goal than we have ever been." (1)

Whether we even want to be there or not is an entirely different matter, but undoubtedly many components of the often envisioned "scholar's workstation" are already in place, and others are being developed at a dazzling rate.

Conducting research, simply put, is a two-step process that entails a) identifying appropriate information and b) ownership of that information. The materials, to simplify again, come in basically two formats, either books or journal articles, which are either printed on paper or stored electronically. The different technological options for identifying research material and for document delivery (discussed below) each lend themselves to different parts of the research process.

3. CD-ROM DATABASES

CD-ROM (Compact Disc-Read Only Memory) technology was developed in late 1984 as an offshoot of the audio compact disc. Since then CD-ROM as a medium for data storage and retrieval has evolved at a rapid pace. In 1986 there were only 48 titles available in this format. By mid-1991, this number had skyrocketed to 1,960 titles (2), and by the end of 1991 there will have been an estimated 2,400 titles.

Especially libraries have eagerly embraced this new technology. A recent survey of all ARL (Association of Research Libraries) member libraries (3) found that 96 percent of them now offer reference use of CD-ROM databases. For the first time, a large number of students and researchers are enjoying the convenience (speed, economy and versatility) of electronic information retrieval because none of the surveyed libraries charge for CD-ROM services. Nearly 38 percent of the libraries have installed CD-ROM LANs (Local Area Networks) -- a technology considered impossible just a few years ago -- to provide access to their frequently more than 30 databases.

An even more recent technological development is the possibility of dial-up or remote access to CD-ROM LANs. According to the survey cited above, only five research libraries besides the University of Hawaii's Hamilton Library currently offer this capability. It is this aspect, of course, which is most attractive in the context of distance research. The University of Hawaii at Manoa has installed three CD-ROM LANs: in Sinclair Library, in the Science and Technology Reference Department of Hamilton Library, and the largest in Hamilton Library's General/Social Sciences and Humanities Reference Department, with 11

different networked databases for journal literature indexes in business, sociology, public affairs, education, and psychology, as well as for indexes to major national newspapers.

Remote access is presently available to the latter from two dedicated nodes on the dial-up module of the LAN for the UH-Hilo library and for the Maui Community College library. The connection is made from the Gandalf Starmaster in Hamilton Library to the UH Computing Center Starmaster and then via a T1 line to the local Starmaster portside in Hilo and on Maui. Two additional nodes are planned for Kona and Kauai. The possibility of providing access to the CD-ROM LAN at Hamilton Library through the UH telecommunication and computing network is also being explored for the future. This would potentially allow remote access for the entire community and for anyone with access to the UH network.

Although most bibliographic CD-ROM databases so far provide only indexing and abstracting to journal literature, there is a definite trend toward full-text, thus enabling users to obtain complete documents. One case in point is UMI's Business Periodicals Ondisc, which holds 240 CD-ROMs in a jukebox configuration. The system contains the full-text of some 400 business journals. A similar full-text project is underway at Information Access Company, with another involving a joint venture between UMI and H. W. Wilson for the social sciences.

4. ONLINE DATABASES

Access (via microcomputer, modem and phone line) to electronic databases loaded at remote host sites of databases vendors has been available since the mid-1970s. The number of individual databases has increased continuously. Just during the past ten years it has gone up from about 600 in 1981 to more than 5,000 in 1991 (4). Until the mid-1980s and the advent of CD-ROMs, online databases were the only option for electronic information retrieval in academic libraries. However, although nearly all research libraries provide access to often several database vendor services, cost has de facto limited their use to faculty, Ph.D. and M.A. candidates -- unless online searches were subsidized by the library.

All of the major vendors charge for online searches according to the pay-as-you-go principle (beyond a subscription fee or a monthly minimum). The cost incurred is a combination of telecommunications charges (ca. $12 per hour), connect time charges for a particular database on the vendor's mainframe (from $35 to $300 per hour) and print or display charges for individual records (15 cents to $120 per item). Most online databases are either numeric, bibliographic or of a directory type and, paralleling a trend in the CD-ROM industry, producers are increasingly offering full-text databases. The following paragraphs briefly highlight some of the major database vendors. For information on other databases and database vendors consult the online directory listed in the Appendix.

4.1 DIALOG INFORMATION SERVICES

DIALOG offers more than 1.3 terrabytes of data in more than 400 different databases covering all subject areas of knowledge. More than 1,700 full-text sources and journal files are available on the system. The initial subscription fee is $45 ($35 from the second year onward) and DIALOG offers a special subscription package called Knowledge Index for 100 of its databases at a fixed fee of $24 per hour. For further information call 1-800-334-2564.

4.2 DATA-STAR

Data-Star, a European-based database vendor, is quick to point out to U.S. customers that the location of their mainframe in Berne, Switzerland, doesn't mean a delay when connecting via SprintNet and underground/sea cable. They have more than 250 databases in all subject areas but are obviously particularly strong in European databases. Data-Star offers a $20 per hour "after dark" discount, which for Hawaii is in effect practically all day long. There is no initial sign-up or annual fee. For further information call 1-800-221-7754.

4.3 BRS

BRS's subscription cost varies depending on the package -- between $75 and $95. At this point, only about 20 percent of its 150 databases are full-text. The coverage is for all subject areas, but is particularly strong in the medical and pharmaceutical fields. For more information call

1-800-289-4277.

4.4 LEXIS/NEXIS

LEXIS/NEXIS, international in scope, is a specialized online vendor for legal, business, news and governmental databases. It offers the full-text of more than 800 journals and other publications including many news wires, SEC filings, the CFR, the full-text of bills, and the Federal Register. The annual subscription is $125. For more information, call 1-800-227-4908.

4.5 STN INTERNATIONAL

STN, the scientific and technical information network, is an online system providing access to more than 100 bibliographic, numeric, structural and full-text databases in all areas of technology and the sciences. The one-time start-up fee is $25. For more information, call 1-800-848-6533.

5. ONLINE PUBLIC ACCESS CATALOGS (OPACs)

Online catalogs are common in libraries. In the survey mentioned above, we found that 98% of all ARL libraries now have an electronic catalog to their library holdings and nearly all of them offer dial-up access. In the last couple of years, however, a new trend has set in and libraries are beginning to load other databases on to their systems. This is also the case at the University of Hawaii.

With the beginning of this year, UH switched over to the CARL system (originally developed by the Colorado Alliance of Research Libraries), mainly because it has that capability. Some of the databases on the system available now include: the Hawaii State Data Book (full-text), the Hawaii Sheet Music Index, the Trust Territory of the Pacific Database, Federal Government Documents Publications (index), and UnCover (an index to over 10,000 journal titles in all subject areas, with coverage beginning with Oct. 1988). UnCover distinguishes itself for two reasons, a) the indexing is extremely current by any standard and b) it allows the user to order the full-text of an article identified in the index, pay for it with a credit card and have it faxed within 24 hours to any fax machine.

ERIC, one of the most heavily used electronic databases, covering all aspects of educational journal literature, will soon also be available on CARL. Loading other commercial databases is being discussed.

The CARL system can also function as a gateway and thus allows access to other local information systems, like ACCESS (the Legislative Information System), Hawaii FYI, and the Hawaii State Library system and to other mainland library systems.

Remote access capability to UH CARL for the Pacific region is also (in addition to the INTERNET discussed below) provided via PEACESAT (see Appendix 2). In recent months, more and more islands have taken advantage of this possibility. However, closer cooperation seems necessary, especially in terms of document delivery to Pacific island nations.

6. OCLC (ONLINE COMPUTER LIBRARY CENTER, INC.)

Located in Dublin, OH, OCLC is a union of more than 13,000 libraries and library systems, including the Asia-Pacific region, providing bibliographic access to more than 33 million records stored on 17 Tandem mainframe computers. The OCLC interlibrary loan subsystem functions as the U.S.'s major electronic book lending clearinghouse and document (journal articles) delivery system for its member libraries, with an average turn-around time of two weeks per item. The lending of books is usually free (except for postage, telecommunication and system use charges), while the average cost for a journal article is about five dollars.

7. RESOURCES ON THE INTERNET

The INTERNET is a vast system of computer networks spanning the globe. While most people may primarily think of it as an electronic mail system, it is much more than that. Some of its other functions are to permit file transfer between different hosts and remote login, which allows connecting to a remote computer. The latter is perhaps the most appealing for researchers.

In 1989, the first library online public access catalogs (OPACs) began to appear on the INTERNET. Since then, several hundred libraries from around the world have provided access to

BEST COPY AVAILABLE

their holdings databases through this network. Institutions thus accessible include, in the U.S.: UC Berkeley's GLADIS, Stanford University's SOCRATES, Harvard University's HOLLIS, the Cornell, Princeton and Columbia universties' online library catalogs, ORBIS at Yale University, entire library systems like MELYL in California and the CARL system discussed earlier; in the U.K.: OLIS at Oxford University and the Cambridge library catalog; in Australia: the Australian National University Library; as well as libraries in Sweden, Germany, Switzerland, and many more. For a listing of library catalogs accessible via the INTERNET (and the procedures for connecting), please refer to the Appendix of this paper; especially handy is the memory resident hypertext program written by Peter Scott from the University of Saskatchewan.

And there is more. What was said about CARL is also true for many other library systems: they don't just have their library's holdings, but often have special indexes, bibliographies and full-text databases. For example: on the Dartmouth College Library System, you will find the full-text of the King James version of the Bible, the full-text of all of Shakespeare's sonnets and the full-text of 33 of Shakespeare's plays (with separate summaries and other value-added features); on the Carnegie-Mellon system, you will find an index to architectural illustrations; on the University of Saskatchewan system, you will find an index to Canadian Business and Current Affairs.

And there is more. And most of it is free - although sometimes perhaps unintentionally: many of the library systems include commercial databases and access to them is usually limited to persons associated with that institution and usually requires a password - but sometimes it doesn't and sometimes the password is rather obvious ....

And there is more. Through the INTERNET, you can access more and more of the commercial online database vendors discussed earlier, like STN and LEXIS/NEXIS and thus save telecommunications charges you would incurr using fee based services like Tymnet or SrintNet (formerly Telenet).

And there is more. There are other databanks available, which are neither part of a library system nor reside on a commercial host, like the ATI-Net (an agricultural market and trading information systems) or OCEANIC (a database for marine sciences) or the NASA space shuttle schedules or a nationwide weather forecast, etc.

And there is more. There is the Cleveland Freenet (and other freenets and bulletin boards), which is a community computer system, operated by Case Western Reserve University, and offers among many, many other things also a full-text database of the United States Supreme Court opinions.

And there is more. Although we don't yet live in the land of Xanadu as envisioned by Ted Nelson for electronic publishing toward a "docuverse", more and more scholarly journals appear in electronic form, and only in electronic form. Please refer to the index listed in the Appendix.

And there is more, to explore on the INTERNET.

8. CONCLUSION

This paper was about possibilities -- not realities. And indeed, there are many viable options for distance research which begin to reduce the time an energy expended on identifying and obtaining research materials so that more time and energy may be expended on their critical analysis.

Incidently, in the course of research for this paper, I came across a reference to a journal article which promised to be of some relevance. Unfortunately the issue had been sent off to the bindery by our library. I could have ordered a copy of the article through UnCover via fax, but it would have cost $ 9.50 ....

But even if cost should turn out not to be a factor in information access, "the fact that it is technically possible for information to be available to everyone at little cost in no way ensures that it will be." (5)

1. ABSTRACT

Integrated multimedia technologies are making possible complex project coordination of widely-scattered entities. This paper addresses pilot application of such techniques for an educational science curriculum program: The Foundational Approaches in Science Teaching (FAST). The International Network for Education in Science and Technology (NEST), which is based on the FAST program, seeks to increase global understanding of the environment and a global ethic of responsibility for nurturing that environment on national and international bases. Current efforts involve extending integrated, multimedia telecommunications resources and techniques to the project development, testing, dissemination, feedback and evaluation phases. Early efforts at such activities on an international basis in NEST are described in this paper.

2. BACKGROUND

2.1 MULTIMEDIA COMPUTER-BASED EDUCATIONAL TELECOMMUNICATIONS (CBET)

Being isolated from all major population centers has stimulated the development and utilization of telecommunication resources in Hawaii. In the early 1970's the University of Hawaii, in cooperation with Pacific basin countries and the United States National Aeronautics and Space Administration (NASA), pioneered in developing a grass-roots, international educational satellite program called Pan-Pacific Education and Communication Experiments by Satellite (PEACESAT). PEACESAT began in 1971 through use of the ATS-1 and ATS-3 communication satellites under the direction of NASA.[1]

An early example of the integrated, multimedia approach was a series of programs based on the American Field Service international student exchange program. Returning students gave live presentations over PEACESAT accompanied by duplicated, colored slides on PAFSPECS (Pan-Pacific PEACESAT Educational Communication System).[2]

Later electronic computer mail provided a convenient, asynchronous messaging capability in planning for multimedia events over PEACESAT or telephone. This began to be used in the early 80's. In the mid 1980's the Hawaii Global TELEclass Project.[3] integrated videophones and electronic mail to enrich foreign language classes in Hawaii and around the world. Students could practice written and spoken communication via computer mail and speakerphones, respectively. NASA's newly-developed agreement to use the GOES3 satellite should make possible a new era of multimedia capabilities for PEACESAT and its users. Not only voice but facsimile, computer data, and video slow scan images can be transmitted quickly to regions throughout much of the Pacific.[4]

These are among the resources foreseen as having potential for coordination and operation of the International Network for Education in Science and Technology (NEST). Originally funded by the Hitachi Foundation, NEST has been establishing links between schools in New Jersey, North Carolina, Maine, Minnesota, Hawaii, Texas, Russia, Singapore, Indonesia, Hungary, and Japan that are currently using the FAST program. It is thought that NEST is the first educational telecommunications project based on a successful, existing science curriculum program. [5]

2.2 INTRODUCTION TO NEST

The International Network for Education in Science and Technology (NEST) project is designed to develop cross-cultural awareness and an international communications network that addresses global environmental concerns and facilitates collegial exchange among science teachers. This three-year project, funded by the Hitachi Foundation, is a collaboration of the Center for Pre-College Programs, New Jersey Institute of Technology (NJIT), and the Curriculum Research & Development Group (CRDG), University of Hawaii (UH).

The objectives of NEST are to

1. establish a network of national and international contacts for collecting, analyzing, and sharing environmental data.

2. develop investigations concerning the environment that will be global in concept and content and can be adapted to various cultures.

3. provide an opportunity to identify and test activities for collection and comparison of globally relevant data.

4. encourage understanding and respect on the part of both students and educators for cultural differences and how they may affect problems and solutions to global concerns

Students involved in the pilot program communicated with one another via the Electronic Information Exchange System (EIES), sharing data they collect on environmental topics such as weather patterns, acid rain, soil analysis, ozone depletion, and similar topics. Data collection is coordinated by the primary sites at the University of Hawaii and New Jersey Institute of Technology.

Participants use the Foundational Approaches in Science Teaching (FAST) program. FAST was developed by the Curriculum Research and Development Group of the University of Hawaii College of Education. FAST is an interdisciplinary, environmental science program which emphasizes foundational concepts and methods of physical, biological, and earth sciences and relates them to practical issues of human use of environments. FAST is an accredited science program used by over 500,000 middle school students in the U.S.A. and overseas. FAST gives students a sense of the operations of our modern, scientific community by directly involving them in processes of inquiry and research.

Videotapes of classes are exchanged to provide a visual image of the students involved and the different environments being studied. Data are collected during the same periods of time, uploaded onto the EIES system, and compared by classes in diverse areas.

NEST invites middle school teachers and their students to share environmental data. Through "hands on" activities science teachers can more readily address current ecological issues and by using telecommunications can give their students valuable technological experience and awareness of global issues.

2.3 PROJECT HISTORY

NEST grew out of previous work at the University of Hawaii and NJIT. Project MENTOR (Marine Education Network to Organize Resources) was an early cooperative science project using telecommunications that began in 1981. Project MENTOR was established by Barbara Klemm and John Southworth at CRDG as part of a National Science Foundation Information Dissemination for Science Education grant. It provided an opportunity to explore possibilities using computer systems and other forms of telecommunications among marine educators in the United States and overseas. [6, 7]

In 1984 Howard Kimmel and Mark O'Shea developed a project with middle school teachers in New Jersey. They began work with the idea of using the Electronic Information Exchange System (EIES) to support the implementation of American Association for the Advancement of Science (AAAS) materials called *Science Resources for Schools* (SRS).[8] Their project, known as the *Middle School Improvement Project* (MSIP) was approved by AAAS as a special dissemination project studying the effects of using workshops plus computer conferencing to implement curriculum activity packets. After the SRS project was completed, Kimmel and O'Shea developed a model for continuing in-service for their teacher group which included:

- Saturday morning workshops held once every three weeks to learn content and explore activities related to one or a few themes
- EIES support to address teacher and student questions and provide for joint data collection
- visits to schools to support the teacher's local efforts in their own environment (political and technical support).

The NEST project evolved from the success of MENTOR, MSIP and the in-service teacher group's curiosity to share their data with other areas of the world. In 1988 Kimmel contacted John Southworth and Donald Young at the Curriculum Research & Development Group (CRDG) of the University of Hawaii to explore interest and ideas for developing a proposal for an international telecommunications project. A three-year grant from the Hitachi Foundation was successfully obtained and in the fall of 1989 the project was launched.

NEST now unites an international network of middle-school teachers and their students using EIES as the communications vehicle and FAST as the instructional base. Project investigations include such topics as rain forest degradation, air and water pollution, solid and toxic waste disposal, demise of species, the greenhouse effect, and other environmental areas with international implications. NEST investigations are designed to supplement the science program, not replace it.

3. NEST OPERATION AND COMPONENTS

3.1 TARGET POPULATION

The target population for this project includes middle-school students and teachers using the FAST program. In FAST these students have already developed the skills of data collection, the ability to analyze and understand the data collected, and an ability to begin to develop an awareness of the global impact of environmental issues. This is an ideal age to impress on students the importance of informed decision making about environmental issues, to develop global awareness of such issues, and to begin to develop an awareness of cultural perspectives on these issues.

FAST was also selected because of the diversity of locations available for data collection. FAST has been named an exemplary science program by the National Science Teachers Association and is a validated project by the National Diffusion Network. It has been adopted by schools in 36 states and is also used in schools in the Virgin Islands,

Pohnpei, Kosrae, Australia, Japan, Abu Dhabi, Singapore, Indonesia, and Hungary. These various locations can provide environmentally diverse data as well as an opportunity to develop global understanding of environmental issues and cultural diversity.

3.2 INTERNATIONAL PARTICIPATION

Three international participants who were experienced FAST teachers, two from the Republic of Singapore and one from Budapest, Hungary, were invited to participate in piloting NEST. Nishinippon Junior College High School in Fukuoku, Japan, Sohseikan Senior High School near Nagasaki, Japan and Gakushuin Senior High School in Tokyo, Japan, were also invited to join NEST in 1990. Moscow schools were successfully involved through the efforts of Southworth. Future potential participants include teachers in France, Jakarta, Micronesia, and Australia.

3.3 FAST

The *Foundational Approaches in Science Teaching* (FAST) program is a second-generation inquiry science curriculum designed specifically for middle-school students. FAST has been designed to enable students to replicate the activities characteristic of the science disciplines at a level appropriate to the developmental stages of 12 to 14 year-olds. Content is organized into three strands called physical science, ecology, and relational study. Relational study focuses on the interrelationships of the science disciplines and the interactions of science and society. The program consists of three, one-year courses intended to be studied sequentially.

The goal of FAST is the development of a scientifically literate student who has 1) the background necessary for understanding the environmental concerns arising in our technological society, and 2) the foundational tools for further study in the sciences. The principle objectives of FAST are to develop thinking skills, laboratory skills, and knowledge of foundational concepts of the disciplines of science. [9]

FAST instructional strategies were designed to take advantage of the major characteristics of middle-school students—their high energy level and curiosity, their need for social interaction, and their developing ability to deal with abstract thinking. Students work in small groups where they are encouraged to talk with one another about their experiences and ideas, thus directing their need to talk toward meaningful communication and learning. The developmental structuring of FAST begins with concrete, real experiences from which students derive concepts and language, thus facilitating their development of abstract thinking. [10]

3.4 FAST and NEST

Of particular importance to the NEST are the ecology and relational study strands of the FAST program. Students learn how to collect environmental data, to analyze it and to report their findings. They also learn how to use reference material to supplement their studies. The relational study strand serves several purposes within the program. Its content is drawn from the fields of philosophy and history of science as well as from the study of current environmental issues. Further, the relational study graphically demonstrates the connections between the sciences, technology, and the world of the citizen. At the end of each of the three courses there is a relational study unit that is designed to cause students to draw on all their experiences in physical science and ecology and to apply their new knowledge to the study of an environmental issue.

Relational study exposes the limitations of scientific knowledge in the arena of social decision making. The input of the sciences is seen as but one of the many factors (moral, ethical, aesthetic, economic, political, and others).

Students using FAST already collect local environmental data on soils, weather, air quality, water quality, food production, incident solar energy, land use, resource depletion, and population growth as part of their studies. However, before NEST no mechanism had been available to enable students to share and compare environmental data. Utilizing the EIES system provides that valuable component.

3.5 EIES

Since the early 1970s scientists and engineers have used wide-area telecommunications as one method of communicating with each other. The Electronic Information Exchange System (EIES), a computerized conferencing system based at the New Jersey Institute of Technology, was developed under National Science Foundation sponsorship specifically for this purpose. Its advantages include participation at the site, time, and pace of the participants' choice, a variety of experts as resources, interaction with peers and experts, a written transcript of the proceedings, and minimal costs compared with telephone, mail, and travel. With the computer used to store and organize their communications, participants are able to carry out a variety of projects despite the fact the they are located in different states and/or countries.

Public access networks [e.g. Sprintnet operated by US Sprint] have many host computers (e.g. EIES) sharing their lines and saving communication costs. In addition, they have local nodes in many towns and cities, thus saving long-distance charges to reach the host computers. Bitnet and Internet are international networks linking educational, governmental and research institutions around the world. Networks such as these are becoming increasingly common in schools which generally subscribe to them for access to electronic mail, computer bulletin boards, private and public data banks, and services that distribute curriculum guides. Once a computer conferencing system is established the potentials for structuring, facilitating, and augmenting the communication and information exchanged among members of a group are virtually unlimited.

4.0 NEST PROGRESS

4.1 1990-1991 ACTIVITY

During the summer of 1990 CRDG developed and distributed a NEST manual. The manual contained instructions for accessing EIES, information about uploading and downloading procedures, selected FAST investigations, a timeline for completing the environmental investigations during the academic year, and information on member sites and international time zones. Additional materials were prepared or purchased and sent to members as needed to facilitate involvement in the project.

Accounts for participants in the electronic conferencing system were established in September 1990. Communications nodes were also established in two locations in North Carolina, one location in Minnesota, one location in Maine, and three schools in Japan in addition to the expansion of sites in New Jersey and Hawaii. Teachers' first log-ins occurred from September to December 1990.

4.2 GREETINGS

The development of confidence and rapport among members is critical to the successful implementation of collaborative activities. [11] This is especially true in electronic communications. With this in mind, "electronic greeting" messages were sent on EIES to provide a warm, personal touch and encourage participants to use the electronic network.

As an additional communications enhancement VHS tapes called "Hello Tapes" were developed at each site. Each teacher and their class introduced themselves and their environment via a brief segment on a videotape. The videotapes were then circulated to the other sites.

4.3 NEST NEWSLETTER

A newsletter published twice a year was established to share ideas among the students. Articles were written by students and sent over EIES to the New Jersey-based editor. Students were encouraged to think "globally" so that an exchange among the culturally diverse participants at the different sites could be maintained.

4.4 PROGRAM IMPLEMENTATION

It seemed appropriate to start the curriculum effort with the New Jersey group of teachers who had worked together previously and had Kimmel and O'Shea close by to help with any questions that arose. The New Jersey teachers began an initial evaluation of activities for students at different locations to share ideas and concerns of a regional and global nature. The selected activities initially included such topics as acid precipitation, water resource management, the greenhouse effect, solid waste management, and oil spills. Several activities involving solid waste management were explored. In one school, various video media and a values clarification slide presentation were used by the students to record perceptions of litter and the importance of a litter free environment. NEST implementation was much slower in areas outside New Jersey due mostly to inexperience with EIES.

5. FORMATIVE STUDY OF THE NEST PROJECT

5.1 INTRODUCTION

In order to evaluate the project's progress and offer recommendations for further development, CRDG conducted a formative study. [12] Two mail surveys and telephone interviews were conducted with each site to determine the strengths and weaknesses of the project.

The research had four general goals:

- to determine the extent to which the project has succeeded in promoting teaching and learning about environmental issues;
- to identify the variables that influence the NEST conference and to compare the growth of the NEST conference with that of other conferences in the EIES system;
- to determine the problems and promises of communicating on-line with other countries;
- to develop recommendations about management of the project and ways to facilitate and motivate participation by drawing upon these findings.

5.2 FINDINGS

Findings were described in three categories—level of conference use, environmental content of exchanges, and member considerations. NEST did provide a channel of communication and exchange of environmental data among members. Of the comments entered in the NEST conference by the end of February 1991, 62% were on environmental issues.

Members perceptions of the project were encouraging. Although many were unable to use EIES efficiently, 100% were enthusiastic and excited about the project. Opinions of international members are unknown, yet their repeated attempts to access EIES indicated interest in the project was still present.

5.3 VARIABLES AFFECTING PARTICIPATION

Three variables appeared to affect NEST participation. These were categorized as technical, social, and topical.

5.3.1 TECHNICAL

Differences in EIES computer training proved a factor in the level of participation during the 1990-91 academic year. The New Jersey teachers working with Kimmel had the opportunity to meet and get EIES training at the New Jersey Institute of Technology. Other participants in NEST were generally unable to receive such training because of their diverse geographic locations. As a result, these participants were less frequently on-line than the New Jersey-based group.

In addition, the accessibility of telecommunications equipment affected rates of participation. Access to EIES can also be seen in terms of cost barriers, convenience barriers, and barriers derived from the degree of previous experience with and knowledge of EIES. These factors affected member participation rates. For example, the most active participants had telecommunications equipment easily available while the least active members reported access to equipment was difficult.

Admittedly, some of the technical problems of telecommunications are inherent in the medium. A characteristic of computer-based conferencing is that messages are stored in the host computer until it is convenient for members to receive them; therefore, the time lapse between the entry of a comment and when it is read by each member is

unpredictable. This implies that it should not be used for information needed immediately. This resulted in two sites reporting they felt "left out" because their requests for help and more information were not responded to until a month after their messages were sent.

Local technical problems were also a factor impeding participation. Teacher participants had varying brands of computers, modems, and software. This made it difficult for CRDG to assist all members having difficulties. Most of these problems were with software. The telecommunications software available today can be confusing and may appear very complicated. Many network companies, TERC for example, are developing their own software so people with general computer experience can use their networks.

Although many previous studies [13,14,15,16,17,18] emphasized the importance of an active and structured moderator for producing successful group discussions, the moderator of the NEST conference was not active. The moderator issued no warm invitations, sent no encouraging messages to compliment individual members or comment on their entries, and did not suggest what they may be uniquely qualified to contribute.

5.3.2 SOCIAL

Most NEST members were not familiar with each other. EIES, however, features a directory that lists names, addresses, a brief description of members, and when members were added to the EIES system. There was a great difference in the activities of members previously familiar with EIES and the new members. All of these new members reported being intimidated by the number and content of messages generated by experienced EIES users within the conferences they viewed.

In addition, unlike previous computer-based communication programs there were no common meetings among members, no regular visits by administrators and few other ways to acquaint teacher participants with procedures.

Since the average rate at which members logged-in was less than once a week, a long period of EIES use was necessary for members to get to know other members through their messages alone. During the telephone interview, teacher participants stated that a common meeting would increase participation. The Hello Tapes and NEST Newsletter were important factors because they acquainted members with EIES and each other.

5.3.3 TOPICAL

Private and conference message topics play a critical role in the beginning of interaction in computer-based communications. [17] In a face-to-face meeting, an introduction, or sheer proximity, may inspire interactions to begin. In computer-based communications proximity is irrelevant and the content of the messages must determine whether interactions will begin.

Participation then rests on topics of discussion that are interesting and relevant for the community of members. Unlike previous studies, NEST focuses on topics from a common science and problems with the topics of study were not found. Sixty-three percent of all teacher participants were trained FAST teachers, and the most active member, a teacher participant not trained in FAST, completed four FAST investigations. Eighty-five percent reported collecting data on target FAST investigations yet only 15% entered the data in the system. Clearly, technical difficulties overshadowed topical problems.

In addition, it should be noted that Kimmel has operated on the assumption that face-to-face contact is essential in establishing a network. Over the next year of the project Kimmel's assumption of personal contact will be tested against the counter assumption that interesting and relevant content will inspire participation.

6. INTERNATIONAL DEVELOPMENTS

6.1 INTRODUCTION

CRDG was largely responsible for the support and progress of the Japanese and Russian participants. Both the Nishinippon and Gakushuin contacts were English teachers and the Sohseikan member was an administrator. It was anticipated they might lose interest or feel left out if science was the only topic of communications. Therefore, CRDG made extra efforts to make them feel welcome.

Although the international communications on EIES were rare, the fact that most were able to access EIES is encouraging. It was also discovered that they had different expectations and uses for the project. Once this was realized, ways to accommodate both the project and the site were considered.

6.2 MULTICULTURAL PERSPECTIVES INTRODUCTORY COMMENTS

It was also important for participants to become aware of the impact of electronic communications on the discussion of different cultures since the technology may tend to blur cultural differences. By its nature the medium precludes the presence of features that constitute the context of face-to-face interactions. These include the relevance of setting, situation, physical attributes of participants, and speech characteristics. Normally such features strongly contribute to the context for not only interpreting the meaning but also to the value of what is being said. [11] Indeed cultures often attribute different meanings to metaphors and other expressive forms of language.

Moreover, different cultures may also develop their own unique adaptations and applications of the technology. Yet, the increasing political and economic-based interdependencies between cultures and nations will require increased intercultural communication and understanding. NEST schools in the U.S. from urban, suburban, and rural areas also provided a cross-section of America with variations in environment and resources. The following are examples of international participation from the USSR, Japan, and the USA.

6.2.1 USSR: MOSCOW SCHOOL TELECOMMUNICATIONS NETWORK

The Soviet Academy of Sciences has been advocating the use of computers and telecommunications for several years. Several entities within the Academy have been working with local schools and community groups to develop international contacts. The Moscow School Telecommunications Project (MoSTNet) is one of them which has been associated with the NEST project during the past two years. [19]

In 1988 the Academy launched an international cooperative project called the New York State - Moscow School Telecommunications Project. Alexander Uvarov has led the project to study the "problem of introduction of new informational technologies into the school and their interaction with the rapidly-developing process of integration "the rapidly-developing process of integration of new content and new educational means with the traditional approaches." [20] In the summer of 1989 a conference held in Moscow gave the participating teachers from both countries the chance to get acquainted personally as well as to begin planning their joint activities.

The project involved use of both asynchronous computer communication with electronic mail as well as synchronous videotelephone exchanges. The computer provided the mainstay of the communication and permitted convenient planning of the periodic videophone exchanges.

Initially, the project involved pairing of schools with sister schools and subsequent exchange of electronic mail by computer networks. Subsequent videophone exchanges were planned for a frequency of two-to-three times a semester. The final mode of experience is seen as that of student and teacher exchanges to permit face-to-face communication.

The development of a "telecomcenter" in the form of MoSTNet took place during the summer of 1989. MoSTNet exists to help tutors, learners and their educators to make good use of the various available new technologies. The center gives courses and workshops as well as consults on all aspects of hardware, software and educational content for networking activities.

An interesting set of criteria for selection and evaluation of student generated projects to lessen the possible contradictions and misunderstandings was developed by MoSTNet.

1) E-mail is of vital importance for cooperative projects.

2) Projects should be jointly-supported endeavors involving both schools.

3) Each side should be prepared to help promote mutual understanding and cooperation on the project.

4) Students should follow the pattern of laboratory researchers as they conceive and organize problem-solving endeavors.

5) Simple, clearly-throught-out projects should be featured.

6) The students should gain knowledge, skills, and attitudes from participation in such projects of a practical nature.

7) Projects must be well-structured and well-defined.

8) The time limit should not exceed 4 months.

9) Projects should be self-supporting and rely on equipment available at the school.

10) The project should be open to all those who are available

6.2.2 JAPAN: SOHSEIKAN HIGH SCHOOL

Sohseikan is a private school with approximately 1,500 students mostly from the Nagasaki Prefecture. A large proportion of students graduating from the school directly join the work force rather than continuing immediately in college. Priorities for the school include telecommunications, information sciences, and English language. There are ten classrooms with about 450 microcomputer terminals linked to their host computer system. There is a library of computer related information in magazine form in the host computer room. The school has a movable satellite receiver to access American and Soviet television and weather satellites. This is used for getting international information and movies from overseas. In the computer education curriculum there are topics of computer graphics, programming, and hardware/software education. The school is wired for closed-circuit television in basically every classroom. The audiovisual room contains the TV system control and studio. There is a learning lab in five of the ten computer classrooms including overhead projection, audio tapes, computer-based attendance, and VCR units. There is an image scanner for computer graphics and a voice analysis system to monitor speech patterns. This extensive list of resources makes Sohseikan among the leaders in use of educational technology at the secondary level in Japan. Because of this, Sohseikan frequently sponsors or hosts computer seminars. In the past year international electronic mail and videophone use have begun.

Junichi Nozato is Sohseikan's telecommunications specialist. He is primarily responsible for the design and set up of its computer system. He designed a computer table which features a collapsible top which doubles as a desk when lowered. He is also responsible for the planning and development of Sohseikan's telecommunication and information science curriculum. Nozato is also the director and adminstrator of the telecommunication and information science curriculum.

6.2.3 TEXAS: SANGER INDEPENDENT SCHOOL DISTRICT

The FAST Program is utilized by over 100 8th grade students at the Sanger Middle School. The 8th grade science teacher, Debbie Bennett, has a fully equipped science lab consisting of the normal science equipment, but also the lab is equipment with a computer that is networked with the campus system. A HAM radio station is presently be installed. The ecology portion of FAST was selected by Sanger because of our involved with the National Weather Service in Fort Worth, Texas. Sanger is a coorporating weather station with students actually running the weather station.

It was also felt that since the Director of Technology, David Moore (eies206), supervises all technology related functions, he should be on the NEST system. With his connections to other systems around the world, Sanger will not only be utilizing the FAST/NEST/EIES2 system, but connecting with other schools to share data.

Both Debbie and David connect to EIES2 via TENET, the new Texas Education Agency Network. This system allows Sanger to connect via Internet to the NEST Network.

6.3 JOINT PROJECTS EXPERIENCES

6.3.1 USSR: MOSTNET

In June 1990 MoSTNet joined the EIES network and took part in an exciting and innovative tri-nation videoteleconference between the USSR, Japan, and Hawaii. This led to periodic EIES exchanges with NEST participants, including publication of Moscow students' articles in the NEST

Newsletter. During the presentation of this project at the 1991 PTC Conference, a group of students and their parents joined the MoSTNet staff until 1 a.m. in the morning to join in via videophone during the PTC session to provide a vivid example of the dynamic potentials of telecommunications for educational projects. [21]

MoSTNet has been developing telecommunications with the concept that the teacher's role will change from that of the main source of information to one of being a partner in the research efforts.

In recent months there has been difficulty in maintaining regular contact due to the change of computer systems from EIES1 and EIES2 as well as network differences. As this article goes to press other NEST project participants are all hoping the economic and technical challenges will not preclude continued activity by those in the USSR.

6.3.2 JAPAN: SOHSEIKAN

For the past three years Sohseikan has had a sister school relationship with the University of Hawaii Laboratory School. In late March of 1991, Alfred Kina went to Sohseikan as the first exchange teacher from the Lab School. Kina instructed English conversation although his college major was Fine Arts. Under the guidance of John H. Southworth, one of his primary aims was to assist the implementation of Sohseikan's newly-subscribed EIES system. Together with Nozato, they successfully accessed EIES surmounting obstacles from budgetary restraints to system accessiblity. They also were able to successfully participate in videophone conferences with the Laboratory School and other continental mainland sites. Although the nature of the videophone conferences included primarily NEST themes, Sohseikan's full participation as a NEST member was limited because the limited English capability junior high school students' and teachers.

Nozato and Kina hurdled many obstacles in successfully linking up to EIES and to implement other telecommunication projects. But in spite of the difficulties encountered in the process, they have come a long way since last March. With Nozato's engineering, electronics and technical knowledge, and Kina's interpersonal relationship skills, they have managed to complement each other's strengths in providing a stimulating, and challenging multimedia telecommunications system. Both agree that the key to a successful telecommunication system is the 'human element'. "One can have the most sophisticated hardware in the world, but if noone uses it , it doesn't mean anything." is one of Kina's favorite sayings. Kina considers himself a bona fide telecommunications specialist because, although he doesn't have the technological background, he is able to successfully plan, coordinate, and moderate telecommunication events.

6.3.3 TEXAS: SANGER

Sanger had some problems implementing the FAST curriculum during the 1991-92 school year. There was a change over of teaching personnel. The potential of FAST is unlimited. The fact that schools from around the world can connect and SHARE date and complete the same experiments is beyond the standard textbook science classes. NEST allows students to DO science, not just read about it. Sanger has not realized the true potential of FAST. In the coming months and years, Sanger believes that students will see the need for science education and see the future life-skills for science exploration.

7. '91-'92 FAST-NEST

Having established the effectiveness during the pilot project last year, the project is expanding into the FAST-NEST project to launch additional FAST sites, activities and personnel.

In the summer of 1991 a number of steps were taken to improve upon the pilot project. Building on the findings from CRDG's formative study, a revised plan for 1991-92 was established. Critical elements for the coming year include 1) determining procedures for using and testing the capabilities of EIES, 2) securing and training a HI-NEST conference moderator, 3) developing and disseminating a HI-NEST manual, and 4) inviting FAST-certified trainers to participate.

A major step has been the retirement of the EIES1 computer and transfer of all operations and users to EIES2. This has been taking a lot of time to retrain EIES1 users and give some training to new FAST-NEST participants.

Invitations have been extended to all FAST-Certified Trainers to begin networking on EIES2. Separate conferences have been set up for the student, teacher and trainer activities. A mix of post, phone, FAX and personal visits have been employed in launching FAST-NEST. It is hoped that the trainers can gain experience and eventually include telecommunications skills and operations as part of the regular training program. New materials are being developed and reviewed while the existing ones are being revised.

New conferences for multicultural holidays and traditions and one for technical projects have been gaining popularity, especially as our number of international users increases.

Plans for continuation are pending development of grants and/or local school funding through budgetary, special projects, or other modes of fund-raising. Hopefully, this will lead to the ability to launch a broader model project as described in the next section.

8. THE HI-NEST PROJECT

The enthusiasm of the NEST pilot project participants and the need for FAST trainers, teachers and students to communicate with one another on environmental and program issues have led NEST developers to expand the project. The expanded project, to be known as HI-NEST, will continue with the national and international communication on environmental themes including more environmental investigations, a new computer-based communication system, additional national and international sites, and a channel of support services for the rapidly increasing population of FAST users.

8.1 COMMON ENVIRONMENTAL SCIENCE PROGRAM

FAST will be the common program uniting project participants nationally and internationally. FAST is already being used by students and teachers in 36 states and various international sites providing a rich diversity of locations for environmental data collection.

FAST has been named an exemplary science program by the National Science Teachers Association and is a validated Project by the National Diffusion Network. It has been adopted by rural, suburban, and urban schools throughout the United States and is also used in schools in the Virgin Islands, Pohnpei, Kosrae, Australia, Japan, Abu Dhabi, Singapore, Indonesia, and Hungary. The diversity of

adoptions demonstrate the program's adaptability to different environments and cultures. These various locations provide opportunities to develop global understanding of environmental issues and cultural diversity.

8.2 ELECTRONIC INFORMATION EXCHANGE SYSTEM

The EIES system used for the pilot project began operation in 1975 and was found by participants to be difficult to use. However, NJIT has developed a new system, EIES 2, which promises to be state of the art and easier to use. EIES 2 was available for use beginning in July 1991 and members of the pilot project were transferred to the new system in August. NJIT distributed a general users manual which will be revised in light of response from users. Advanced use of EIES 2 is currently being investigated and NJIT has establish separate conferences for the HI-NEST project. The first conference will be for reporting, analyzing and discussing student data, the second for project teachers to communicate with one another, and the third for FAST-certified trainers to confer with one another and with teachers they have trained. Membership will be determined by the project moderator.

8.3 THE HI-NEXT MODEL

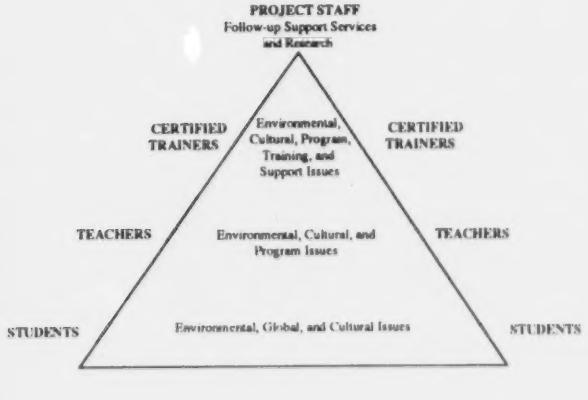
The FAST program is growing at an unprecedented rate. Over fifty teacher institutes were conducted during the summer of 1991. This brings the number of FAST-trained teachers to nearly 4000 and the number of FAST students in 1991-92 to over 290,000. Projected figures indicate that by 1995 over 8,000 teachers will be teaching FAST to more than 600,000 students.

Project staff view HI-NEST as a powerful support tool to ensure the success of FAST as it grows and provide for meaningful interactions among FAST and nonFAST teachers. HI-NEST will provide a progressive network whereby project staff can more readily support all teachers and trainers involved with the program. Not only will teachers and students benefit from an understanding of global issues and communications technology, they will be linked with their peers from around the world.

The HI-NEST project is based on a hierarchy of users engaging in increasingly complex and rich sets of interactions. These are described in Figure 1 below.

FIGURE 1

HI–NEST MODEL



8.4 STUDENT CONFERENCE

Through the student conference HI-NEST provides students the opportunity to share environmental data and observations, collaborate on ideas, and conduct research with other students throughout the United States and around the world. In so doing, students develop an awareness of the global environment and multicultural perspectives in dealing with global issues. In addition, they replicate the process of scientific inquiry as it exists today, giving them the experience of practicing scientists.

8.5 TEACHER CONFERENCE

Participating teachers working with their students share the benefits of conducting research and sharing environmental data on a national and global basis. In addition, HI-NEST provides a network whereby teachers can communicate regularly with one another and with project staff about program issues.

8.6 CERTIFIED TRAINER CONFERENCE

Teacher institutes and follow-up support services are an integral part of the FAST program. Classroom sets of materials are only made available to teachers who have been trained to use them. FAST teacher institutes are a combination of theory and application which includes intensive study and engagement with the FAST program. Teacher institutes are conducted by FAST project staff and certified trainers. These trainers are experienced, highly motivated FAST teachers who have had additional training from FAST experts in conducting teacher institutes.

The HI-NEST certified trainer conference will serve multiple purposes. First, since all FAST-certified trainers are also classroom teachers, they too will share in the excitement with their students of engaging in study of globally relevant issues and communicating with other FAST students and teachers worldwide. Second, the HI-NEST will create a network of certified trainers who can communicate regularly with one another and with project staff about training and support issues relevant to providing timely and up-to-date teacher institutes. Third, HI-NEST will provide an opportunity for certified trainers to communicate with and support those teachers that they trained in FAST teacher institutes. Fourth, all FAST-certified trainers will be active EIES users and will incorporate EIES training into the FAST teacher institutes they conduct.

9. CONCLUDING REMARKS

Thus FAST-NEST and HI-NEST are providing practical models for applications and testing of developing modes and techniques of integrated multimedia telecommunications. This project, while related to a specific science education activity, could play an important role in research and development of ways in which telecommunications can aid many types of educational, business, governmental, and community service programs. It is hoped the coming years will involve development of effective partnerships with business and other educational entities that would benefit from the sharing and exchange of information that is emerging from this new and innovative endeavor based upon international cooperation.

12. AUTHOR BIODATA

John H. Southworth is Educational Associate with the Curriculum Research and Development Group, University of Hawaii College of Education in Honolulu, Hawaii, USA. He has been active for over two decades in educational telecommunications program research and development. He served as Senior Investigator of the Hawaii Global TELE-class Project of the Hawaii State Department of Education. He was invited to participate in the East/West Seminars in New Technologies in Education that have taken place in the USSR and Czechoslovakia in 1988, 1990 and 1991. He is currently technical services coordinator for the FAST-NEST Project.

Mary Gullickson-Morfitt is FAST Science Program In-service Coordinator with the Curriculum Research and Development Group, University of Hawaii College of Education in Honolulu, Hawaii, USA. She has over five years experience in teaching of secondary science and the middle school FAST program. She has worked in the Summer Science Enrichment Program of the Curriculum Research and Development Group. She has been involved with instructional development, science education and educational telecommunications. Her Masters thesis was based on the development of the FAST-NEST program.

David L. Moore is Director of Technology with the Sanger Independent School District in Sanger, Texas, USA. There he has been involved with all aspects of technology: computers, telecommunications, and computer curriculum. He is a Master Trainer with the Texas Educational Network, Apple Computer Educator, and Texas Computer Education Association Computer Adminstrator of the Year (1990-91). He has worked closely with Telecommunications and Informatics Laboratory at the Texas Center for Educational Technology to bring multimedia educational telecommunications to the Sanger schools. He has become a regular educational user of the UH PEACESAT system via the ATS-3 satellite.

Junichi Nozato is Computer Education Specialist for the Sohseikan Intermediate and High School in Isahaya Nagasaki Prefecture, Japan. He was an Engineer with Mitsubishi Electronics and later a science teacher at Nagasaki Intermediate School. Nozato presently oversees the direction of the computer education department at Sohseikan. He was instrumental in the design and planning of the computer classrooms. The collapsible-top computer terminal tables, which also double as a flat-top desk, is of his design. In addition, he is active in national and international telecommunications projects.

Alexander Uvarov is Director of the Moscow School Telecommunications Network (MoSTNet) of the Soviet Academy of Sciences in Moscow, USSR. He was an organizer of the first Soviet Academy of Sciences co-sponsored East/West Seminar in New Technologies in 1988. As Director of MoSTNet he has coordinated telecommunications projects between schools in Moscow and New York State (starting in 1988) and Hawaii (starting in 1990).

Donald B. Young is Co-Director of the FAST Program, Curriculum Research and Development Group, University of Hawaii College of Education in Honolulu, Hawaii, USA. He has been involved for 19 years in the development, dissemination, and evaluation of the FAST program. His doctoral thesis was based on learning styles associated with the success of FAST instruction in middle schools. His recent research activities have been in program implementation and maintenance in schools and multidimensional assessment.

Basic Telecommunications Needs Model:
A Methodology for Assessing Information and Communication Poverty

Dr. Mark Balnaves, Mr. Peter Caputi
Royal Melbourne Institute of Technology, Australia
Ms. Kirsty Williamson
University of Melbourne, Australia

The research for this paper was commissioned by the Telecom Australia Consumer Council (TACC) and funded by Telecom Australia

Abstract

The expressions 'information rich' and 'information poor' are now commonplace in the telecommunications research lexicon. Managers, policymakers and community agencies, however, do not have comprehensive conceptual and methodological tools at their disposal to identify information and communication needs and the 'information poor'. This paper attempts to address some of these concerns. A model and methods for investigating information and communication poverty are proposed.

> There is, in essence, no sociology of telecommunications which has generated understanding of users and their uses to which regulators can assign value (Dervin & Shields 1990: 4).

Despite a large body of literature on information and communication needs there remains an absence of persuasive evidence about those needs or how to identify those needs. Existing studies have failed to assist managers, policymakers and consumer groups because researchers have tended to impose their own definitions of 'needs' upon the people they were studying (Dervin & Shields, 1990). The methodology proposed in this paper draws on the social theory of Hindess (1988) and the constructivist approach of Balnaves and Caputi (in press) and on participatory approaches to the study of information and communication needs. The first part of the paper provides a background to information and communication needs research. The second part of the paper outlines the concept of basic or common information and communication needs. The third section of the paper presents a theoretical model and methods relevant to the assessment of those needs. The final section of the paper outlines preliminary results from a pilot study.

Information and Communication Needs Research

It is beyond the scope of this paper to conduct a general survey of all the works on information and communication needs. Dervin and Nilan (1986) and Kunz, Rittel and Schwuchow (1976) have conducted detailed reviews of the literature on conceptual and methodological issues of information need. A review of the literature by Williamson (1984) suggests that there is no agreement on what constitutes an information or communication need or how one should proceed to develop uniform methods for assessment of such needs (see also, Crane, 1971; Crawford, 1978; Dunn, Noble & Peguillan, 1977; Horne, 1979; Leupolt,1983; Lin & Garvey, 1972; Lipetz, 1970; Martyn, 1974; Voos, 1969; Wilson, 1981; Wood, 1969). There are definitional problems for both information and need. Faibisoff and Ely (1978) noted that a review of thirty-nine definitions of information science included only eight definitions of 'information' and that no element was common to even two of these. Numerous definitions have evolved. Attempts have been made to distinguish between 'data' and 'information' (see, for example, Maguire, Lovelace & Kench, 1976), and between 'knowledge' and 'information' (see, for example, Childers, 1975; King & Palmour, 1981).

The general research focus in studies of information and communication needs has not been 'user-oriented'. As Dervin and Nilan (1986) pointed out, most of the approaches have been constrained by definitions of what needs are and they have been limited to examining behaviour primarily within user intersections with systems: 'In fact, it could be said that the needs of interest are system needs not user needs' (p.11). Earlier researchers asked respondents to name problems or questions for which information had been needed (see, for example, Macbeth & Hitchens, 1977; Warner *et al.*, 1973; Williamson, 1977). Dervin *et al.* (1976) were critical of such studies, concluding that the word 'information' may well constrain individuals to name concerns that they believe can be dealt with in the confines of existing information systems, the very systems citizens indicate that they rarely use.

While not directly addressing the above issues, the work of Tinker (1989), Claisse and Rowe (1987), Cooper (1987), Moyal (1989) and others indicate that the starting point in a study of information and communication needs is the *forms of thought* or *specialised techniques* available to people or to groups in the conduct of the business of daily life. 'Most of the specialized tools used in academic work, for example, make use of the relatively commonplace skills of reading and writing. Within a society individuals and groups may differ in the specialized tools they are able to use or are in a position to acquire' (Hindess, 1988, p.97). Those who miss out on more commonplace tools, like literacy, may be severely disadvantaged when it comes to the use or acquisition of other techniques. For example, Claisse and Rowe (1987) have pointed out that the telephone is a 'management tool of daily life' and that 'special habits' have attached themselves to telecommunications usage. The acquisition of these special habits has consequences for the acquisition of others. It is also the case that not everybody will be equally placed to benefit from the efficiencies gained in use of space and time or the kinds of specialised techniques that have become associated with telecommunications and computers. Similarly, not everybody will be able to acquire the kinds of skills that those technologies require.

Telecommunications may also promote skills in social support, as Moyal (1989) has shown in analysis of the feminine culture of the telephone. Aronson (1971) used the expression 'telephone neighbourhoods' or 'psychological neighbourhoods' to describe such networks. A network might consist 'of a group of elderly widows living alone

who maintain scheduled daily telephone contacts as a means of ensuring the safety, health, and emotional security of the group's member' (p.162).

Skills and techniques that develop around telecommunications usage, whether they are related to solving problems, answering questions or promoting social support, are legitimate areas for investigation. It would also seem that information and communication needs are conceptually tied to these skills and techniques or, more appropriately, to what Derr (1983) has called 'information purposes'. Derr argued that the concepts 'information' and 'purpose' are intimately related. He said that there is a distinction between 'information want' and 'information need'. An information want involves aspects of knowing where the person concerned has no *legitimate* purpose. For example, a person might want information about a neighbour's activities out of idle curiosity, but that is not sufficient for saying that the person needs that information. Conversely, lacking information is not a sufficient condition for saying it is needed. Many physicians recommend an annual physical examination for persons forty years of age or older. A ten-year old may not be familiar with the physician's recommendation but such lack 'is not sufficient for our saying that it is needed' (Derr, 1983, p.273). An 'information need' requires a legitimate purpose. If a person was middle aged, we would say that she needed the information regarding the physician's recommendation regardless of whether she wanted it or not. 'Information need' refers to a relationship which obtains between information and the information purposes of individuals: 'It is an objective condition rather than a psychological state' (Derr, 1983, p.276).

The idea of information purpose is also related to the notion of *being informed* (Balnaves, 1990). As Jonas (1953) has suggested, people are purposeful beings and in order to be purposeful they must be 'in-formation' (p.192). However, it is necessary to distinguish between the *means of becoming informed*, such as information and communication technology, and *being informed*, which is a characteristic of individuals and groups.

Information and Communication 'Commons'

In Australia, consumer groups and community agencies have actively developed a model of 'social equity as equality'. This model incorporates the idea of identifying the information and communication 'commons' of Australian citizens with the idea of social equity (Balnaves & Richardson, 1990). The model also suggests that a distinction should be made between individual needs and individual circumstances and *basic* telecommunications needs. Individual circumstances such as physical or social disabilities may affect a person or a group's capacity to meet basic telecommunications needs. For example, a low-income, elderly and disabled person who has eyesight difficulty might require additional attachments to the phone in order to make a phone call. The ability to make a call may be termed basic, but the individual circumstances in this case deny the person access to the phone, firstly because they may not be able to afford attachments to remedy the access problem and, secondly, because they do not have the physical wherewithal to use the phone (Balnaves & Richardson, 1990). Basic telecommunications needs, however, are those needs which are common to all of us. We might call *access* to the traditional telephone, for example, a basic telecommunications need because so many information and communication purposes are dependent upon it. Similarly, there may be a level of telecommunications *usage* that is common to all of us. Cooper (1987), for instance, identified three telephone calls a day as essential.

However, there is no empirical evidence about common information and communication purposes and basic telecommunications needs. It might be the case that the traditional phone and three calls a day are not sufficient to meet basic telecommunications needs. Policymakers at present do not have the conceptual and methodological tools necessary for identifying common information and communication purposes and basic telecommunications needs.

Individual and Collective Needs

The evaluative notion of 'telecommunications needs' or 'information and communication needs' suggested in this paper draws from both prescriptive and consensual approaches to social policy. Firstly, *there are individual differences in needs*. For example, the elderly and disabled or rural residents will have different needs from those in urban areas. Secondly, *there are also collective similarities in need and in the acquisition of specialised techniques related to telecommunications*. The ability of all people to answer questions efficiently and cheaply may be called a collective need or a common information purpose. For example, PRESTEL, the British version of videotext, embodies large economies of scale. The more answers the user obtains, the lower the cost per answer. Indeed, costs could become negative. This situation occurs for subscribers of consumer reports or other product testing magazines when the savings that users obtain from product-test details in the magazine exceed the cost of a subscription (Maynes, 1983).

Maynes' (1983) work suggests that it is possible to identify *gains* or *losses* involved in meeting or not meeting information and communication needs. There may be *monetary losses* incurred by people or businesses who pay more than necessary for meeting telecommunications needs. There may be losses incurred by people or businesses obtaining *less than was needed* to meet telecommunications needs. There may also be losses from the fact that people or businesses were *unable to discern*, and hence purchase, the price-quality combination best satisfying telecommunications needs. For example, an elderly person who cannot afford to obtain answers to everyday life questions in the most efficient manner may be at a disadvantage compared with another who can. A person with access to an efficient videotext system (which PRESTEL was not), as mentioned earlier, can gain economies of scale.

Information and Communication Poverty

There would appear to be four aspects of any definition of information and communication poverty. The first aspect of definition suggests that the concepts 'information' and 'communication' are related to the concepts *being informed* and *being associated* . The second aspect of definition suggests that telecommunications have an obvious relationship to *conducting the business of everyday life*. The third aspect suggests that losses might be incurred in not meeting information and communications needs. Losses might occur because of insufficient resources, like income, or because some portion of a resource, for example, income, is absorbed in other useful or wasteful ways. Losses might also occur because of inaccessibility to particular technologies . Lack of access might occur because of corporate reasons (the provider is incapable of delivering the technology); physical reasons (an individual is incapable of using the technology); psychological reasons (an individual

is unwilling to accept alternatives or does not know that particular choices are available); or intellectual reasons (an individual does not have the knowledge necessary to use the technology). The final aspect of definition of information and communication poverty would suggest that there are common information and communication purposes. The purpose of the authors' research is to identify the *commonality of these needs.*

A Telecommunications Needs Model

It is possible to suggest five components of a theoretical model for assessing information and communication needs. Firstly, there are those situations or *sites* in which telecommunications might be required. The authors will refer to these as Domestic or Business Sites (S). A site might be a family household, but it might also be a corporation such as Telecom or a plumbing business which uses mobile phones. The concept of site, therefore, can be applied to a nomadic aboriginal tribe, whereas the concept of 'household' cannot. Sites are defined by the kinds of relationships involved and the kinds of specialised techniques and forms of thought employed in those sites. Secondly, there is the ability to conduct the business of everyday life. Everyday Life Activities (ELA) have been the primary focus of urban information needs studies which have identified topics such as neighbourhood, consumer, housing and maintenance, employment, education and schooling, transportation, recreation and culture, financial matters, public assistance, discrimination, health, legal, crime and safety (Chen & Hernon, 1981). Thirdly, there are common aspects to everyday life activities which are dependent upon information and communication purposes (P), that is, *being informed* and *being associated.* Fourthly, while citizens have information and communication purposes, the technologies themselves *serve a purpose.* Thus, the characteristics of the technologies (T) must be part of any assessment of information and communication needs. These technologies may be relatively simple, such as the traditional phone, or more complex services such as Personal Communication Networks. Finally, these technologies, in turn, enable efficiencies to be gained in use of space and time (E). Telecommunications technologies allow people to save time and travel, for example, in making appointments at a hairdresser or in contacting an employer for a job.

The proposed model contains all the elements that one would find in a situation where a person wanted to become informed or to participate in the business of daily life. These elements would form the basis of any development and assessment of a methodology used to investigate information and communication needs. A methodology which addressed both the psychological and sociological dimensions of information and communication needs in the sense discussed above, including the gains and losses incurred in not meeting those needs, would provide policymakers with an index of information and communication poverty.

An Index of Information and Communication Poverty

The authors have suggested that it is possible to identify gains and losses entailed in meeting information and communication needs and that these gains and losses are real in their consequences. Five methods (community profiles, diaries and focussed interviews, substitution matrices, repertory grids and community organisation) are proposed to investigate these gains and losses, in the context of the model presented above.

Community Profiles are profiles of sites and the demographic circumstances in which individuals or groups live. A profile includes understanding the discursive conditions (specialised techniques and forms of thought) available to individuals or groups. For example, Balnaves and Caputi (in press) have combined the personal constructivist approach of Kelly (1955) and the social theoretic approach of Hindess (1988) to develop a detailed notion of both 'personal' and 'corporate' constructs and sites. Hindess argued that a capacity to make decisions is an integral part of anything that might be called an actor. State agencies, political parties, football clubs, churches and tenants' associations are all examples of actors in the minimal sense. 'They all have means of reaching decisions and of acting on at least some of them' (p.46). The actions of a tenants' association, a corporate site, is of course, always dependent upon the actions of others such as managers, elected officers, employees and other organisations. Hindess argued that there are actors other than human individuals, 'some of whom play an important part in the modern world, but that classes and societies are not among them' (p.47). His concern was with the identifiable means of making decisions, which may include, among others, specialised forms of analysis and techniques such as Aristotelean physics, ritual, mythology, and writing systems. The concept of sites and community profiles advanced in this paper builds on the work of Hindess and others. The kinds of questions people pose for themselves and the conclusions they reach will often depend on the forms of thought or specialised techniques available to them. The expression 'corporate constructs' will be used to refer to such techniques (see Balnaves & Caputi (in press) for a more detailed discussion). They are corporate in the sense that they are the product of numerous individuals. A corporate actor, like a football club, is dependent on corporate constructs like accounting techniques, management techniques, leadership techniques, and so on, and on the individuals *using* such techniques.

Diaries and Focussed Interviews, at the individual level, enables people to record their information and communication purposes whether or not they have telecommunications services. If individuals have a telephone, then incoming and outgoing telecommunications calls would be recorded. The diaries are simply a record of the frequency and nature of information and communication purposes.

The *Substitution Matrix*, a technique developed by the authors, allows individuals to indicate the extent to which information and communication purposes could have been carried out in any other way, that is, could be *substituted.* These matrices will indicate the degree to which people perceive telecommunications to be essential to their lives. Personal constructs can also be derived from the matrices and used in repertory grids (Kelly, 1955).

The application of *Repertory Grids* (Kelly, 1955) to the study of information and communication needs is new. A grid allows a researcher to see how one idea (for example, a perception of telecommunications technology) has linkages with other ideas, and how one form of telecommunications technology (for example, the mobile phone) is perceived as similar to, yet different from other forms of technology. The grids may be used to examine different psychological dimensions of information and communication purposes in the context of traditional and future telecommunications technologies and to derive data on perceptions of acceptability of different forms of communications, such as perceptions of flexibility, speed, and degree of privacy and

efficiency. This approach will indicate which groups are likely to adopt innovative technologies and which groups are likely to be resistant to change. It is envisaged that the notion of 'corporate construct' will be included in the grid methodology, but this work is still in its developmental stages in the pilot work conducted by the authors.

Community Organisation enables community participation in definition of its needs. One of the important aspects of the methodology proposed in this paper includes participation by individuals, consumer groups and community agencies in the research process itself. Organisations such as the Telecom Australia Consumer Council (TACC) are ready made means of community organisation. With empirical evidence about information and communication needs, associations like the TACC will have knowledge necessary to assess the competence or efficiency of different organisational forms and their component parts (for example, judging the actions of Telecom itself and other agencies involved in the definition of Community Service Obligations, such as AUSTEL, and private businesses). The issue of competency is also relevant to the problem of constructing a wider political system that allows representation of interests that may be either poorly organised or without the power to lobby from positions of prestige or possession of resources (Hirst, 1986) (for a discussion on community organisation see also Brager, Sprecht & Torczyner, 1987; Kramer & Sprecht, 1983; Musick & Hooyman, 1976; Stein, 1986)

Incorporation of both corporate and personal constructs into Hindess and Kellyan theory and the use of repertory grids in the analysis of information and communication needs represents a major conceptual and methodological advance in communication theory. The substitution matrices are also new techniques. Community organisation complements a methodological approach which is user-centred and relational in character. The methods do not simply involve taking a snapshot of a person's situation and subsequently deriving a list of needs. Rather, the methods try to capture the dynamic nature of how people meet their information and communication needs and to indicate the gains and losses that might be incurred if those needs are, or are not, met.

At what point can one say that we have discovered common information and communication needs? To answer this question it is worthwhile providing a brief hypothetical description of how some of the methods work.

Let us start with a personal and a community profile. Consider a disabled seventy-five-year-old social security pensioner; no private transport; own house in the outer western suburbs of Melbourne; belongs to local bowls club; veterans association; local church group; living alone; no tertiary education; no other major assets; Anglo-Saxon; previous employment boiler-maker; wife dead; contacts with close relatives. Public transport system (trains and buses) is available; local health centre; no local library; industry intensive suburb; median income under $35,000 (and so on). These are demographic characteristics in the community profile.

Diaries would be given to the pensioner to record incoming and outgoing telecommunications activities (or in the absence of telecommunications, incoming and outgoing information and communication purposes). The substitution matrix would elicit which purposes were considered essential and which could not be substituted by any other means. For example, the pensioner has a traditional telephone and records a purpose as 'using the phone to make banking transactions'. He notes that this purpose cannot be substituted because of his disability. He finds it difficult to walk to the bank to conduct his banking business. In this case the traditional phone appears to be essential to mobility. However, the personal construct 'mobility-rigidity' comparing the traditional phone with a cordless phone and a mobile phone may be presented to the pensioner for further analysis. When considering the construct, the pensioner might state that the traditional phone is in fact a restriction on mobility when compared with other technologies. For example, the pensioner may find it difficult to walk from one room to the next where the traditional phone is located. Such a difficulty may be overcome were a cordless or a mobile phone is available. Further prompting highlights that the pensioner has developed *strategies* of coping with the traditional phone and these strategies may be dependent on factors in the *domestic site*.

The pensioner may not have been aware of the existence of alternative technologies such as mobile phones (cf Tinker's 1989 findings). The pensioner's lack of knowledge about alternative telecommunications might be related to 'corporate constructs', such as literacy, which affect acquisition of such knowledge, restricting the ability to become informed. Of course, corporate constructs may also be responsible for resistance to change. The grid itself would have provided knowledge about alternative technologies and highlighted what the pensioner then perceived to be a *loss* in mobility, that is to say, when the utility of the traditional phone was compared with that of alternative technologies the pensioner perceived the traditional phone to be less useful or in fact 'rigid'. What the pensioner reveals is that it is not the traditional phone that is essential or necessary, but rather the strategies for compensating for lack of mobility. Indeed, there would be an increase in 'efficiency' if the pensioner were to have a cordless or mobile phone. This example illustrates the operation of substitution matrices and repertory grids and, to some extent, corporate constructs.

Let us now compare the pensioner with a twenty-five-year-old young professional in a different domestic site. The twenty-five-year-old may rate the construct 'mobility-rigidity' differently, for example, she may think that the cordless phone also lacks mobility, given that it can only be used in a range of 50 metres. In terms of their everyday life activities, both the pensioner and the young professional have *similar* information and communication purposes, for example, the need to do banking. The difference between the young person and the pensioner is that the young person can substitute walking to the bank for using the telephone, whereas the pensioner cannot. The point here is that for the pensioner the mobility is a far more important factor, even though the 25-year old perceives the traditional telephone to be 'rigid'.

The repertory grid and the substitution matrix provide a personal subjective point of view in usage of telecommunications, or any other service and activity in the community. However, there is also an *objective, corporate point of view*, that may suggest limitations to any personal strategies which are employed in particular situations. This last point needs further clarification. Literacy in this case is a *corporate construct* (a specialised technique). The pensioner, if illiterate, may argue that 'I don't necessarily need to be literate to survive in Australian society. I can develop strategies to overcome most, if not all, the difficulties associated with being illiterate'. The answer highlights some of the limitations associated with a subjective point of view. There are consequences involved in being illiterate that *personal construal* does not adequately address. For

example, there may be, potentially, loss of income, loss of job, restrictions on social life, and so on. In this case the pensioner may find it difficult to find out about alternative technologies let alone how to use them.

The purpose of the methods is to enable researchers to assess information and communication needs and to derive an index of information and communication poverty. The concept of basic or common telecommunications needs (BTN) is based on the relationships between the five components of the telecommunications needs model (S, ELA, P, T and E).

The index derived from the model and the methods indicates gains and losses incurred by individuals in the absence or presence of certain telecommunications technologies. These losses or gains may be: (i) tangible, such as gains in efficiency; or, (ii) psychological or social nature, such as maintaining or improving support networks.

Pilot Study

The model and methods proposed in this study make possible the development of a framework which provides a clear conceptual understanding of 'basic telecommunications needs' and the development of a methodology which measures those needs in both a qualitative and a quantitative sense. The methodology has as its starting point an analysis of 'information' and 'communication needs'.

A pilot study to test the model and methods took place over a period of six weeks during July and August 1991 in conjuction with preliminary fieldwork on the information-seeking behaviour of older adults conducted by a doctoral student. Older adults were chosen as the target group because numbers are growing rapidly in Australia, as in all developed countries of the world. A comparison of the older adults with two younger people was included in the study.

Sample (and Site) Details

Ten older adults, some very frail and living in special accommodation, others robust, active and living in their own homes, were chosen for the pilot study. The ages of the two males and eight females ranged from 60 to 92, four between 60-69 years of age, four between 70-79 and two between 80 and 92. Snowball sampling, a nonprobability technique, was used to develop a network of representative contacts. Other than the three in the special accommodation, who were hand-picked by the supervisor, all participants were personally known to the researchers. Half were well educated - to diploma or degree level. Former careers included accountacy, teaching, engineering, secretarial/clerical. Four were pensioners and six non-pensioners. Two had quite severe disabilities (diabetes and heart conditions). Whilst we do not believe the participants are necessarily typical of their age groups, we believe that we needed to use alert and competent participants for the pilot. The two younger participants were both aged 20, university students and living with their parents.

In order to gain an understanding of present telecommunications use and knowledge, participants were asked about the telecommunications equipment used in their homes and about the types of equipment they know are presently available or soon to be available. Seven (including the two young people) had only one conventional phone; one had a push button phone; two had both a conventional phone and a push button phone with memory; one had a push button phone with memory and a FAX machine. This last respondent, an engineer, still works part time as a consultant. He estimated that 10 per cent of his telecommunications use is for business purposes.

Knowledge of present and future availability of telecommunications equipment varied. Resopndents had at least heard of cordless and mobile phones and FAX machines, although most had never used them. Some of the older women participants said they were wary of all new machines and could not imagine using a FAX machine. The two older men indicated the best knowledge of present equipment available (better than that of the younger people), although even they seemed unaware of new developments in the field (for example, digital systems which allow more than one call to be taken on a line).

Procedure

Diaries (one for incoming and one for outgoing calls) were delivered to each participant in early July. Participants were given personal briefings on how the diaries should be kept over the two-week period required. At the end of the recording period the diaries were collected and analysed in preparation for the interviews, which began about a week after the diaries were collected.

The interviews tooks an average of two hours (minimum one-and-a-half hours; maximum three-and-a-half hours). Each of the BTN instruments was tested, along with those to be used for the doctoral student's research. We took the approach that with such a complicated piece of research which is using such a wide range of instruments, adjustments should be made if considered necessary during the pilot. Where problems arose during the trials, changes were made or clarifications were provided as soon as consultation could take place amongst members of the team.

Diaries

There was wide variation in the number of calls made and received by participants over the two-week period. The minimum number of calls made was three, the maximum 56. For incoming calls the minimum was five, the maximum 46. Table 1 presents the number of calls for each participant.

TABLE 1
Number of Calls Made and Received by Participants

Person	Outgoing*		Incoming*	
	Local	STD	Local	STD
		Older Adults		
1	13	-	22	-
2	10	1	5	3 (+1ISD)
3	13	8	12	3
3 (FAX)	2	2(ISD)	-	3(ISD)
4	11	-	7	2
5	10	1	10	2
6	14	-	15	3 (+1ISD)
7	20	-	17	-
8	8	2	13	1
9	3	-	5	-
10	56	8	46	10
		Young People		
11	33	-	30	1
12	15	-	10	-

*Includes only successful calls plus the first attempt at a call which was never made (because number was engaged or did not answer).

Respondents were asked to note the purpose or the purposes of each call made. Both outgoing and incoming calls fell into the following categories:

Family network: Calls to or from family members, where family contact and support were involved. Some of these calls were also included in other categories; for example, recreation, business and investment.

Social network: Calls to or from friends and neighbours, where social contact and support were involved. Calls in this category were also often included in other categories, for example, recreation, health.

Voluntary services provided by participants: Included such activities as working bees, assisting family members with voluntary labour. Sometimes these services were related to particular professional expertise, for example, a teacher of shorthand providing an appropriate entry for an Australian dictionary. Arrangements for babysitting grandchildren were included in 'family network' calls.

Investment or business related: Included matters related to the maintenance of income, for example, maintenance on properties rented to tenants.

Services sought, offered to, or received by participants or by their family or friends: Most calls involved the seeking of services by participants, for example taxi services, services from chemists, furniture removalists, banks, libraries. Older adults with mobility problems particularly used the phone to request services.

Paid employment: both the younger participants and two of the older adults were involved in part-time paid employment and amde or received calls associated with this.

Recreation: Included theatre and restaurant bookings as well as participation in clubs and sporting arrangements (often also recorded in 'family network' or 'social network'), but not private social functions which were coded in the social network category only.

Travel: Included holiday as well as everyday travel, for example, booking a hire car for a holiday.

Health: Most calls were inquiries about family members and friends who were ill and are also recorded in 'family network' and 'social network' categories. One call was to a professional for health information. Calls to make doctors' appointments are recorded in the 'services sought' category.

Legal: Most calls were discussions of legal issues with family members. Two of the older adults have family members who are solicitors.

Continuing education: Calls concerned courses in which some of the older adults were interested.

Concessions: The one calls made concerned the over-60s card.

Table 2 sets out the above purposes together with the numbers of outgoing and incoming calls made with those purposes.

TABLE 2
Purposes of Calls Made or Received

Purpose	Outgoing		Incoming	
	Older	Young	Older	Young
Family network	51	1	77	2
Social network	47	44	60	36
Voluntary services	7	-	15	-
Investment or business	11	-	8	-
Services sought, offered to or received	43	-	6	1
Paid employment	6 (+3 fax)	3	4 (+ 3 fax)	2
Recreation	20 (+ 1 fax)	1	17	-
Travel	2	-	3	-
Health	17	-	8	-
Legal	2	-	5	-
Continuing education	1	-	2	-
Concesssions	1	-	-	-
Other	1	-	1	-

From Table 2 it can be seen that, for older adults, the largest number of calls were to or from family members. While calls to or from friends (the social network) were the next largest category, outgoing calls regarding services were almost as numerous. It seems that older adults, especially those with limited mobility, are very dependent on the phone for obtaining services. Purposes such as the organisation of recreation, the discussion of investments and business and the provision of voluntary services emerged strongly for older adults, although many of the calls involved were made to family or friends. Clearly there was often an overlap between information and communication needs. The tendency for people to rely on information providers who are psychologically most accessible appears to be confimed (Wilson, 1977; Chen & Hernon, 1982; Williamson, 1984).

The purposes for which the young people used the phone were, in some ways, in stark contrast to those of the older adults. The young people used the phone almost solely for social purposes (although one cannot rely on a sample of two). It will be interesting to see if these trends are confirmed in the next stage of the research.

Substitution Matrices

In an attempt to gauge the importance of the telephone for each of the outgoing calls recorded in the diaries, a substitution matrix was used. Participants were asked if there were any other ways they could have achieved the purpose or purposes they had in mind.

Although the administration proved a very repetitive exercise, especially for the participant with 56 outgoing calls, the substitution matrix appears to be a very useful instrument. From it we gained insight into each person's philosophy or rationale of telephone use, together with some indication of the degree of need involved. The usefulness should be enhanced when we further develop the instrument for collection of data on individuals and sites.

While participants seldom saw satisfactory alternatives to the telephone for fulfilling the purposes recorded in their diaries,

some participants used the telephone more sparingly than others. One of the young participants said that she visited people in preference to ringing because she had no privacy at home. On the other hand, the other young participant used the phone regularly and made more than twice as many calls as the other young person. One of the older adults, the participant with the FAX machine, said that he always had in mind the economics of alternative methods of communication. Others, particularly those in special accommodation and those without a car, had fewer alternatives to consider.

The possible alternatives which participants frequently mentioned were personal visits and letters. The former were mostly dismissed because, in the circumstances, they were considered to be inconvenient, time consuming and expensive. Distance was frequently mentioned. Participants also sometimes saw a phone call as a way of avoiding more pesonal intrusion. Letters were mostly considered to be too slow as a form of communication. The lack of immediate response was also emphasised. Several participants mentioned that it is not possible to discuss things by letter.

It was from the substitution matrices that most of the constructs for the repertory grids emerged.

Repertory Grids

The use of grid techniques in the study of information and communication needs enables the researcher to explore individual differences and collective similarities among perceptions of telecommunications technologies. The nature of these differences and similarities may highlight psychological gains and losses associated wiht the use or absence of these technologies.

A repertory grid was administered to twelve participants. Each grid consisted of eight elements and eight constructs.The elements listed across the top of the grid included Conventional Phone, Cordless Phone, Mobile Phone, Personal Visit, Letter by Post, Hand Delivered Letter, FAX and Lettergram. The constructs listed at the side of the grid in bi-polar form included Written-Oral, Personal-Impersonal, Direct-Indirect, Cheap-Expensive, Private-Public, Convenient-Inconvenient, Fast-Slow, Acceptable-Unacceptable. The bi-polar constructs were derived from the substitution matrices and represent the way participants construe the similarities and differences of the forms of communications. Participants were asked to rate each construct on a five point scale. For example, one of the participants, 'Margot', rated the conventional phone '2' along the construct 'personal-impersonal', indicating that to her the conventional phone is a personal mode of communication.

Of the twelve repertory grids, only three had common constructs and elements. It is the commonalities among these three grids that we will examine here. The three grids were compared using multidimensional scaling, a common technique for analysing multiple repertory grids. The elements and constructs were represented jointly in the solution. The multidimensional scaling solution is a best-fitting representation of how elements and constructs relate to each other.

Several constructs and elements grouped together. For example, the three elements conventional phone, cordless phone and mobile phone clustered together, that is to say, all three participants viewed these forms of communication in a similar way. These three elements were located close to the pole 'oral' of the construct written-oral, an obvious interpretation is that the three participants in the study viewed the phone as an oral communication medium.

The elements FAX and lettergram also formed a cluster. This cluster was located close to the constructs personal-impersonal, fast-slow and direct-indirect in the solution. In general, communications via FAX and lettergram were perceived by the participants as fast, but also impersonal in nature. Interestingly, personal visits and hand delivered letters were seen to be acceptable, convenient and direct means of communication, whereas FAX and lettergrams were not. Telephone technologies were, in comparison, construed as acceptable.

One implication of these repertory grids for telecommunications managers is the possibility that FAX technologies have failed to be seen as relevant and acceptable among the elderly. It is important to note, however, that the results presented here are constrained by sample size and difficulties that some participants had in interpreting constructs. These difficulties are themselves useful in developing further the application of repertory grids to various audiences.

What is missing in this presentation of the repertory grids is the relationship between the personal constructs and corporate constructs of the domestic site. Some aspects of that relationship were discussed in the body of the text.

ORGANIZATION RESTRUCTURING: FITTING A STRATEGIC FRAMEWORK

HARVEY LEONG
NYNEX WORLDWIDE SERVICES GROUP
NEW YORK, U.S.A.

ABSTRACT

The challenge of integrating a telecommunications company's home base with its worldwide operation can be met with a strategic framework. Elements of a framework include a shared mission, values, priorities, business focus, financial objectives and an appropriate organizational structure. Factors driving organization structure include customer needs, regulatory requirements and culture of the firm. The strategic framework of NYNEX will be reviewed as a model.

In the past, most telecommunications enterprises organized and managed on a functional basis to effect internal efficiencies. Those were less volatile times. However, in our home market in the Northeastern part of the United States, we today have technology and regulatory change bringing ever increasing competition. Moreover, the recessionary economy along with maturing markets has lowered growth rates to low single digit numbers. On the other hand, the lure of high growth opportunities in countries outside the United States has spurred development efforts to make investments in new markets where we can use our core competencies.

To manage this changing environment and effect the desired results in its home territory and overseas investments, a telecommunications enterprise must have a strong foundation. This foundation must provide the support and direction for its people both at home and abroad.

MISSION

First, an enterprise's foundation needs -- more than ever -- a clear mission with a core set of values. At NYNEX, we have a clear mission to be:

A World-Class Leader in Helping People to Communicate Using Information Networks and Services

A world-class leader sustains excellence over time in those markets in which it chooses to compete. Helping people means our customers will always be people, not computers talking to computers, but people using computers to talk to other people. We are a service business sensitive to human needs and responsive to people.

VALUES/PRIORITIES

The foundation on which all of our businesses stands is a common set of values and priorities.

NYNEX's core set of values is followed by all its companies and people, i.e., quality, ethics and caring for the individual.

We have been reneving our commitment to quality and making it an integral part of how we meet the requirements of our customers. Each year our Chairman recognizes individuals or groups with a special Chairman's Award for Quality.

We have renewed our commitment to ethical business conduct. Along with the establishment of an Office of Ethics and Business Conduct, we have a strong code of business conduct which our people know and follow.

We have renewed our commitment to caring for the individual. We have established a dialogue with our employees and other stakeholders such as regulators, legislators, community leaders and the media, and we are working to strengthen those relationships and the trust necessary for our success. One outcome of this improved dialogue with employees is the early signing of our labor contracts well before their expiration dates.

All of our businesses worldwide follow one set of priorities, i.e., customer satisfaction, cost competitiveness, earnings growth and employee empowerment. These priorities are the keys to our success in all our activities.

Customer satisfaction depends on a dialogue with our customers. We expect all of our businesses to continually survey their customers and respond to survey findings.

Cost competitiveness is absolutely necessary in today's competitive environment given the rapid changes in technology and regulation. We require all of our business units to gather industry data and perform benchmarking studies on an annual basis.

Earnings growth creates the funding and confidence necessary for further growth.

Employee empowerment reflects a trust in our people to "do the right thing". This, coupled with the quality process, is a powerful force for change at NYNEX.

LINES OF BUSINESS

NYNEX has defined and is focusing on four key lines of business through which we serve our customers, apply our core competencies and create value for our shareholders. Moreover, in any market and in any country we choose to enter, we intend to be the best in these businesses. They are:

Building and operating wireline networks. This area covers our activities in privatizations of telecommunications companies, building value-added networks, global networks and CATV. These businesses are built off our core telecommunications competencies from our home region.

Building and operating wireless networks. In this business, cellular networks remain our primary focus in our home territory and in our worldwide activities. Other related wireless networks services also fall in this business area.

Data base management and information delivery. In this area, we manage large data bases of telephone subscribers for our Yellow pages advertising business. In addition, we manage our clients' customer data bases in our direct marketing and telemarketing businesses.

Information systems consulting, development, operations and software services. The development and operation of information systems is a core competency of NYNEX. This is reflected in the wide array of companies to service our customers worldwide.

FINANCIAL

The overall financial goal of our enterprise is to create and enhance shareowner value, both in the short and long term. While in the past, we have done much to enter new businesses to effect higher earnings growth, our present objective is to create greater value from our existing businesses.

At NYNEX, our business development process began in 1984 when we were divested from AT&T. Over the past eight years, we have worked hard to establish material businesses in each of our lines of business. We developed these business both through acquisition and through internal growth. The price of our business development activities during the start up phase was earnings dilution. Today, our objective is to manage growth and create a steady increase in shareholder value.

By following our priorities - customer satisfaction, cost competitiveness, earnings growth and employee empowerment - in each of the markets we serve and in all of our businesses, we have a common worldwide mechanism for creating and enhancing shareowner value.

ORGANIZATION

NYNEX has organized itself into two major business groups, i.e., the Telecommunications Group and the Worldwide Services Group. This organizational formation was driven by both business and regulatory considerations.

The Telecommunications group is responsible for New York Telephone Company and New England Telephone Company, both located in our home territory in the Northeastern part of the United States. Our remaining businesses fall within our Worldwide Services Group. Companies in this Group operate both in our home territory and in markets throughout the world.

In earlier times, we had relied on teamwork to build synergistic relationships among all our companies. With the creation of the two Groups, we are able to bring a more concentrated business focus between specific companies in closely related businesses, as well as provide common leadership.

Moreover, we are also able to alleviate any regulatory concerns arising from close relationships between the regulated and unregulated parts of our business.

SUMMARY

As the worldwide telecommunications industry continues its rapid change, we can expect NYNEX's organization structure to respond to these new challenges. We expect that these challenges will cause changes within each of the Groups, but changes in NYNEX's overall corporate structure will be much slower.

Our mission, values and priorities will remain a constant guide for our people at NYNEX.

MAINTAINING SUBSCRIBER LOYALTY DURING DEREGULATION

Deborah G. Arnold
GTE Hawaiian Tel
Honolulu, Hawaii USA

1. ABSTRACT

As PTT's face deregulation, liberalization of services, privatization, and the threat of competition, the importance of preparing the subscriber base so as to minimize the impact on future revenues and profits increases. Opening up lines of communication with the customer base before these changes occur is the key to success.

2. INTRODUCTION

Change. The word can bring fear into the heart of the bravest manager. But it can also open the doors to new opportunities for success for those who know how to manage it. As telephone administrations face the forced changes brought about by privatization, liberalization and deregulation, which interpretation of the word "change" will apply? Will competition mean lost customers or stronger service? Does deregulation threaten or challenge employees? Will regulators and politicians be seen as enemies or friends?

To a great extent, the answers to those questions lie in management's ability to properly communicate the effects of new policies even before they happen. Countries throughout the world are experiencing or planning for structural and regulatory changes in the way monopoly services like telecommunications are provided. Some governments hope to realize lump sum gains from selling off these assets; others hope introducing competition will improve service and lower costs for the general public. There are many stages of progress in implementing these ideas, and much value can be gained by learning from the experiences of those who have taken one approach or another.

At GTE, for example, the changes in U.S. regulations have had a tremendous effect. The Customer Premise Equipment market has seen competitors come and go, and GTE has had to develop innovative network services to offset competition and meet customer needs. At GTE's Hawaiian Tel subsidiary, the only U.S. local exchange company permitted to carry international long distance traffic, market share plummeted when toll competition was introduced, and a long hard battle ensued to win it back. GTE's subsidiary in the Northern Marianas, Micronesian Tel, also had to deal with competition in the long distance market, while at the same time adjusting to operating under new foreign ownership.

Being among the first to have to face these changes, these companies had to develop innovative programs and strategies to maintain customer loyalty, while at the same time restructuring their profit base. Again, the key to success in each of these cases was implementing a clear communications strategy to a variety of audiences.

3. THE FOUR "W's" OF COMMUNICATING CHANGE

WHY does change need at be communicated at all? WHO needs to know? WHAT needs to be said? WHEN is the right time? All these questions must be considered in developing a communications strategy.

3.1 Why?

There are many reasons why a strategy needs to be developed and implemented. One of the most basic is that "if you don't, someone else will!" Being first with the information that is presented is critical to maintaining that influential position expected of the incumbent organization. The administration that everyone has dealt with and is familiar with has the built-in advantage of credibility. The information coming from this source should be the most

trusted. Giving that power up to a competitor, regulator or even the press puts the administration in a defensive position. Maintaining control over the content and timing of what goes out is essential to achieving objectives.

Often these types of changes require the administration to incur new costs as networks are upgraded, salesforces are built up, and new services are introduced. Preparing the public for rate restructuring that often accompanies these investments is another important reason why a strategy is needed.

An administration facing these issues is also liable to have a very anxious workforce. The grapevine runs rampant in times of change, and unless clear, timely information is coming from the company, this can lead to incorrect rumors circulating, valuable employees leaving, and a reduction in productivity. Any chance of attracting new employees is also weakened if the administration becomes perceived as a "bad place to work."

Maintaining a competitive edge, preparing the rate base for future investments, attracting and keeping employees-- some or all of these reasons may apply to each local situation and need to be considered in developing a communications plan.

3.2 Who?

It's tempting to think one piece of information can get wide distribution and answer everyone's questions. Unfortunately, an administration has many "audiences" for what it has to say, and each of them will interpret the same message differently. For example, a communication that talks about plans to revitalize the bottom line with new investments and streamlined operations will excite potential investors but may totally offend the general public who feel they have to pay for it and worry employees panicked about job security.

The answer then is to segment all the possible groups and come up with a communications strategy for each. Examples of these audiences include: residential customers and the general public, business customers, employees, regulators and politicians, investors, and the press. If appropriate, these can be broken down into even smaller groups, i.e., large businesses vs. small companies.

Once the audiences are identified, their specific needs can be analyzed, and the proper messages and programs can be developed to make sure these people get the information they need to maintain their confidence in the administration and feel comfortable about the changes ahead.

3.3 What?

There are a few general messages and some very specific ones that need to be sent to the target audiences. During any regulatory change, the bottom line of what people are going to want to know is "how will it affect me and my pocketbook?" And again, the answer is going to be different for everyone. To a marketing employee who will see increased commissions from new sales, change could mean an improved salary, but for those employees in an operating area trying to control expenses, it could mean cutbacks or a lower raise next year. Customers may have to pay higher rates for some services, yet see benefits from new products and higher quality of existing services. The administration must prepare each message carefully to highlight the benefits to the target audience and downplay any adversities. Learning from the experiences in other countries and sharing this information locally can assist in allaying fears and emphasizing the positive side of change.

The audiences are segmented, their requirements are identified, and the messages are prepared. The next step is to determine the right vehicles to spread the word. These could include press releases and bill inserts to reach the general public, face-to-face meetings and handouts for employees or executive interviews in the business press. Getting employees up to speed on the issues and positive about the effects of upcoming changes is an important part of any strategy. Employee confidence carries to friends and family who look to them as "telecommunications experts." Employees can also be an effective resource as a Speakers Bureau. Training the good public speakers and making them available for community meetings and events multiplies the number of people who can spread the right word.

Not all communications should be one-way however. The organization which is most successful at managing change is the one that LISTENS as well as speaks. Feedback from each

of the audiences must be obtained to help adjust ongoing communications and determine which messages are successful. Customers and employees especially need ways to express their concerns, get quick answers and find reassurance. Some methods that can be used include surveys, suggestion boxes, customer panels and "hotline" numbers to call.

Finally, all suggestions must be recognized, and action has to be taken. Responsiveness gives the administration credibility and builds trust and loyalty more than anything else.

3.4 When?

Should the new regulations be announced before this process starts? Does the first news editorial have to appear before a reply is drafted? Do enough employees have to quit to make executives recognize they have a problem? The answer to all these questions is NO. And the answers to "When does a communications plan need to be developed?" and "When should messages go out?" are IT'S NEVER TOO EARLY and IT'S NEVER TOO OFTEN.
Start now!

4. Micronesian Tel Experience

GTE Hawaiian Tel's subsidiary in the Commonwealth of the Northern Mariana Islands (CNMI) is a good case study of how to apply these techniques to a company in flux.

4.1 Situation

In the late Seventies, the islands of Saipan, Rota and Tinian were on the verge of unprecedented economic growth. Tourism was beginning to boom, and the infrastructure needed to support this expansion was sorely lacking. The local telecommunications operation was having trouble keeping up with demand for basic service, let alone meeting the more sophisticated requirements of expanding businesses. GTE Hawaiian Tel (HTC) purchased the company in 1981 and began a huge capital expansion that continues to this day. Facilities were completely overhauled, and by 1986 a new digital system was in place. Today, Micronesian Telecommunications Corporation (MTC) has two gateway switches, underground cable, two new earth stations, and microwave radio systems.

But ten years ago, HTC and MTC had a lot more than service and technical problems to fix. For one thing, there was an image problem. It wasn't that MTC had a bad image--even worse, it had no image at all! People thought of it as the "silent" phone company, and took it for granted as they struggled to deal with its bureaucracy and uneven service. Employees came and went. There was little training or incentive to stay, so turnover was extremely high. Also, both employees and subscribers alike were concerned about having foreign investors and worried about the changes that could occur. As if this weren't enough to deal with, competition in the equipment and international toll markets began in the mid-eighties.

4.2 Communications Strategies

Weighing all these factors, the management at both HTC and MTC gathered to work out a communications plan designed to overcome the fears of the public, instill enthusiasm in employees and give businesses confidence in the improvements to come.

The messages they selected to communicate included:

- MTC was dedicated to becoming a quality, full service provider
- Foreign investors were not "taking over" to threaten the work environment
- There were growth opportunities for additional local employment
- Competition would benefit subscribers bringing new services and lower prices
- MTC would need capital to make improvements

Each of these was then tailored to various audiences, and the best methods to get them across were implemented.

4.2.1 Residential Communications

For residential customers and the general public, the main theme that was communicated was *"MTC has people you know bringing you more efficient service."* It was important to emphasize that local employees were still going to be around, and that, once trained, they would be the ones to make improvements happen. One of

the most effective ways MTC got this message across was to use their own employees in new television and print advertising. A corporate video was also made that showed MTC people in their work environments. Company officials took every opportunity they could to give newspaper interviews about the changes to come and praise the experiences in Hawaii that would be used as a model and transferred to Saipan. To get immediate feedback, a customer suggestion box was installed in the main office, and subscribers were encouraged to give their comments.

4.2.2 Business Communications

Business customers were hoping for improved service and "one stop shopping." Unlike residents, they didn't particularly care whether local people were involved; they just wanted results. MTC sent out a strong message that said *"We are going to be your quality, full service provider."* This was preached at Rotary Club meetings, delivered through the Chamber of Commerce, printed in business publications, and even discussed at face to face meetings between MTC officials and their largest customers.

4.2.3 Employee Communications

One of the most important yet most difficult audiences that had to be reached was current employees. Job security had been a fact of life, and change was particularly threatening. There was little pressure to get the job done, and often extra services weren't charged to keep subscribers happy. This had caused spiraling expenses and resulted in a lackadaisical workforce. MTC's message, then was twofold: *"We care about you and want to help you develop. We all have a stake in the bottom line."*

The first step in getting the message across was to hold a series of individual work group meetings and explain how the company made money. The emphasis was on how revenues were collected and how employees' time was translated into expense dollars. This set the stage for getting employees' input on how to improve the financial picture, and Employee Involvement groups were formed to develop suggestions. MTC selected an outstanding employee who was interested in furthering her education and sponsored her to attend a university in Hawaii. This also sent a strong message to the rest of the group that MTC was serious about investing in its people. A special annual kick-off event was planned to provide some excitement and give management another forum to emphasize the benefits of change. Then once employee attitudes were changed, they were encouraged to participate in community events and help spread the word. MTC sponsored a beach clean-up that made employees feel good about their company while at the same time impressing the local community with the dedication and commitment of MTC employees to improving their home.

4.2.4 Government Communications

Local politicians and government regulators were asked to *"Invest in our efficiency."* Their concerns about losing local employment opportunities were allayed, and the benefits of community involvement were seen in the employees' activities. This group needed a lot of one-on-one communication, and senior management was called upon to make sure the proper meetings were held.

4.2.5 Media Communications

Last, but not least, MTC made a concerted effort to get the press on its side. *"You'll be the first to know"* was clearly demonstrated in both speech and practice. They were invited to all product announcements and ceremonies dedicating new facilities. A press release on the planned network expansion was given wide distribution, and key employees were made available for interviews on future investments. The press was even invited to the annual employee kick-offs so they would feel like "one of the team."

4.3 Results

These and many other programs contributed to the success MTC has experienced over the last ten years. It has gone from a sleepy little company with 2200 subscribers and a waiting list of 1500 in 1981 to a state-of-the-art corporation serving over 10,000 customers. Employee turnover has been reduced, and MTC enjoys excellent relations with the press and government regulators. MTC's CPE business continues to grow at a solid rate, and international long distance is highly profitable. This was accomplished by delivering on promised actions and successfully meeting communications goals:

- prepare the public for new investments
- keep good employees and attract new ones
- demonstrate the benefits of change

5.0 GTE Hawaiian Tel Experience

MTC's parent company, GTE Hawaiian Tel, was successful in Saipan because it had already faced many of the same problems by going through deregulation in Hawaii. A lot of the lessons learned were applied to the situation in the CNMI, and thus problems were avoided.

Hawaii felt the full brunt of the break-up of the U.S. telecommunications empires. After the regulatory dust settled, GTE Hawaiian Tel found itself in the unusual position of maintaining its monopoly in local service, being prohibited from offering long distance between Hawaii and the Mainland U.S., but able to freely compete with its international toll business. Equipment was fully deregulated, and competition in both toll and equipment was fierce. Other pressures were being forced upon the Company as well. Prices had to be rebalanced, and major rate cases had to be brought before the Public Utilities Commission. Expenses had to be streamlined to compete more effectively, and employees were being shuffled around. Some positions were even eliminated.

HTC went through the same planning as discussed for MTC, but came up with some unique programs that were right for the larger market of the State of Hawaii.

5.1 Public Programs

For many years, Hawaiian Tel had been taking a monthly survey of residential customers to get feedback on its sales and service activities. Facing all these changes, it was now time to take more aggressive action to correct the problems that were being identified and let people know of improvements. HTC set up a new department reporting directly to the President of the company called Consumer Affairs and chartered it to take whatever action was needed to improve customer communications. A "hotline" was installed for the public to call whenever they weren't satisfied with the response they were getting by going through normal channels. The hotline staff was committed to getting an answer back to the customer immediately. An interesting side note to this program is that what started out as a complaint center eventually became a way for customers to call and say thank you, compliment specific employees and make suggestions. The company was seeing positive benefits already!

HTC also wanted more specific feedback during change. To achieve this, a customer panel made up of residential and small business people was formed who met with different company officials once a quarter and gave their opinion on new products and services. HTC could also learn how the general public felt about issues by talking with this group and getting their reaction.

5.2 Business Programs

Similar programs were implemented for the business market as for the residential customers. A separate survey was taken each month for larger businesses, and a panel just for business customers and their specific issues met separately from the consumer panel. HTC realized that these customers, who accounted for the bulk of revenues and were the most vulnerable to competition, needed special handling.

Service became the differentiating strategy. Service Advocates were identified from the operations groups and assigned to the forty largest customers. These people were called for expedited attention in case of a problem, and they also met regularly with their customers to develop service plans to meet forecasted growth. Executives were "assigned" to the large accounts too to strengthen business relationships between HTC and the business community. Smaller customers were served by yet another program called the Small Business Advocate. Here lower level supervisors volunteered to visit each of Hawaii's 10,000 small businesses and ask for feedback on how the quality of service could be improved. Customers were impressed with all these quality improvement programs, and HTC's image became synonymous with service.

5.3 Employee Programs

As always, employees comprised one of the most important audiences to address. HTC concentrated on

developing plans and programs that would alleviate employee concerns and encourage them to be proactive participants in implementing improvements. Employee involvement was introduced not just as a fancy buzzword, but as a way of life. A process was put in place to ensure employees with ideas and suggestions had the ability to get themselves heard and action taken. A detailed survey was taken that encouraged feedback on a wide range of subjects, including pay levels, recognition, communications, and benefits. Resulting action plans started at the top, with senior management's compensation based on how well they were implemented.

Management was encouraged to get out of their offices and keep in touch with the day-to-day business. "Breakfast with the Boss" and skip level meetings helped cut through the chain of command and ensure the messages of change were delivered straight from the top all the way through the ranks. These and many other programs got employees involved early on in the process of change. Once a feeling of trust was developed, it was much easier to deliver news, both good and bad.

5.4 Community Programs

The employees in turn were then used as excellent spokespeople within the community. Volunteers spoke at local meetings, organized community work days and helped out at various events and activities-- all in the name of HTC. Through its Volunteer Initiatives Program, the company even made funds available for employees to support community programs in which they were personally involved.

Since much of the new competition was from the U.S. mainland, HTC developed a media strategy to reinforce its local image. Television commercials with Hawaiian music and ocean scenery reminded the public of HTC's roots, and when HTC's 100th anniversary rolled around, the company developed a year-long celebration that further emphasized its longevity and solidity.

As a result of all of these programs, GTE Hawaiian Tel is a very different company today than it was prior to deregulation in 1983. It has managed to adjust to the changing telecommunications environment and emerge as a financially healthy corporation with a quality service image.

6.0 Summary

There are many fast decisions which have to be made during a period of change, and it's tempting to overlook the importance of taking the time to tell customers and employees alike what they are and why they were made. However, lack of communication up front means a big price to pay later on. Disgruntled customers look to competitors, investors move on to other opportunities, and valued employees leave. A simple communications strategy implemented in a timely manner can prevent loss of business during deregulation and maintain loyalty from both the public and employees.

Empirical Measurement of Strategic Telecommunications Linkages with Customers, Suppliers, and Business Partners

Edward M. Roche

South Orange, New Jersey 07079

1. ABSTRACT

This paper reports on the results of a survey of U.S. and European corporations to examine and measure interorganizational linkages between the firm, its suppliers, its customers and other business partners. Strategic telecommunications linkages were measured according to the number of megabytes being transmitted and the amount of time these linkages have been operational. In addition, examination is made of *which* functions of the organization are responsible for the linkages by looking at the role of purchasing & manufacturing; marketing & sales; distribution & service; and research & development. The data is broken out for each of these categories. The three types of critical strategic linkages studied are firm-to-customer, firm-to-supplier, and firm-to-business partner.

2. INTRODUCTION

This report is based on the results of a June 1990 survey mailed to several thousand corporations, primarily in North America. Approximately 60 responses were received, including surveys returned and in-depth telephone interviews with telecommunications managers. The survey covered a wide range of telecommunications issues.

3. THE CHANGING ROLE OF TELECOMMUNICATIONS IN THE FIRM

There are three major forces of change facing the telecommunications professional. First of all, there is rapid change in the general avilability of services which might be purchased for the firm. Second, the underlying hardware and software systems being made available is increasing the number of options for configuring networks. Finally, the nature of general business strategy is changing so that the telecommunications function, which has heretofore has played a primarily internal role in the firm is now being asked to implement networks on the exterior of the firm as it interlinks with its environment. These three forces of change are producing an unprecendented amount of turmoil in the role of the telecommunications manager.

Telecommunications may provide the critical linkages which tie together different parts of today's firm as it moves towards heavier use of computerization in its business activities. More and more information workers spend their days in front of computer display terminals, communicating not only with their local data processing facilities, but with workers at many different geographic locations. From long-distance, even international, networks to campus and local area networks, telecommunications is the corporate nervous system making it possible to automate almost all major functions in the bureaucratic infrastructure of today's firm.

It is now no longer necessary to contenplate having different duplicate databases located in several locations. Now, a single large relational database can be accessed through the telecommunications system. Some major multinational corporations are presently consolidating their data centers into regional "mega centers", and this is driven at least in part by new possibilities in telecommunications. There are reported cases of firms consolidating their entire worldwide operations into single "global" data centers.(1)

The *scope* of automation is increasing as well, because the growing number of linkages make it possible to merge even more applications into clusters of automation. With each new wave of investment, data processing is pulling together more and more critical business processes and tying them together through telecommunications-based linkages of computer systems.

3.1. THE EMERGING ROLE OF STRATEGIC LINKAGES

We have seen over this last decade the beginning of a movement towards formation of strategic linkages. The idea for these linkages began in the early 1980's, when a few companies placed computer terminals in

512

PERCENT OF STRATEGIC LINKAGES WITH SUPPLIERS, CUSTOMERS AND BUSINESS PARTNERS REPORTED BY DIFFERENT FUNCTIONAL AREAS

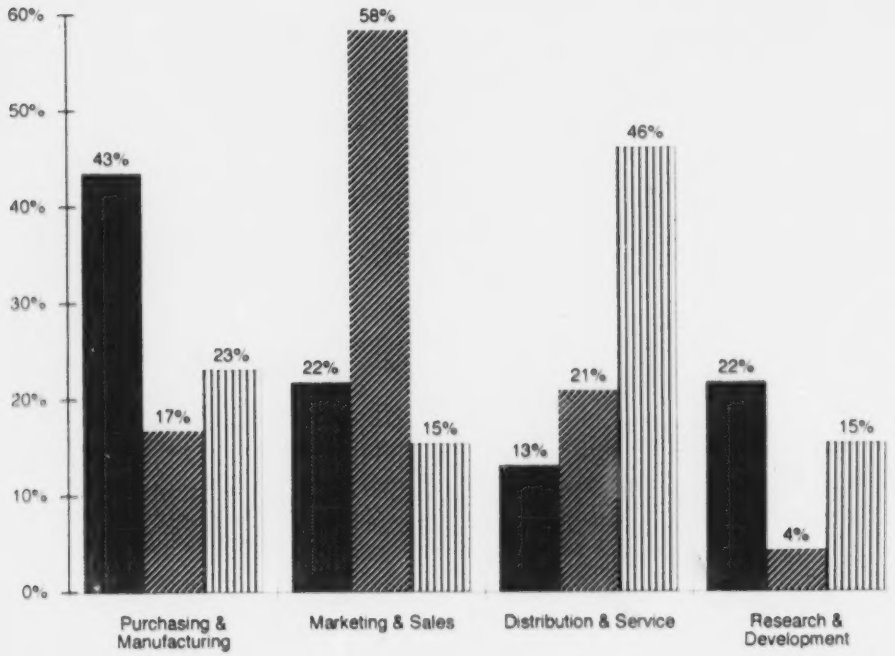

Figure 1

the offices of their customers, but it has taken until the end of the decade before we find that the practice is becoming widespread. Strategic linkages with suppliers, customers, and even business partners are ushering in an entirely new role for telecommunications.

Strategic linkages are based on the general theory of the value added chain as applied to the automation of various informational transactions throughout the business process. The firm is viewed as being a processor of inputs into outputs and the value of the outputs minus the value of the inputs is the value added of the business process under consideration. Although in Europe, the value added tax (VAT) has been a common method of taxation for years, the concept of the value added chain has been slow to take hold in North America. The value added chain model links the firm, its suppliers and customers.(2)

As applied to telecommunications, value added chain theory is associated with building networks to move commercial information between the firm, its suppliers and its customers. For example, home banking systems in which the customers link into the the bank through using a telecommunications linkage, is an example of a *forward* value added chain linkage. For just-in-time inventory control in the manufacturing process, telecommunications-based linkages with suppliers is an example of a *backward* value added chain linkage. According to the theory, once a firm builds telecommunications-based linkages along the value added chain, it is more difficult for competitors to break into the business since the firms will have to bear the extra expense of switching to a new relationship.(3) This "information bonding" erects switching costs which act as a barrier to entry against competitors.

In addition to supplier and customer linkages, a third class of telecommunications-based strategies has grown up: interorganizational systems with business partners.(4) These are telecommunications-based arrangements in which all basic trade documentation is telecommunicated from firm to firm through a shared network. EDI is just one example of an entire class of phenomena in this area. The result should be a general acceleration of the bureaucratic processes associated with trade and manufacturing.

4. METHODOLOGY

This study is based on survey of telecommunications managers in large corporations located primarily in the United States. Although several surveys were sent to companies located in Europe, the overall pattern of the European responses was not significantly different so as to be able to change the results. The survey responses were followed up with telephone interviews in which additional information was gained. The research process lasted approximately 9 months during 1990.

4.1. IDENTIFICATION OF SAMPLE

The study started with a large mailing list of MIS and telecommunications managers located in both large (Fortune 500) and medium-sized corporations throughout the United States. From this list, a random sample of approximately 3,000 companies was selected to receive the survey. Before mailing, this list was checked to ensure that it represented a reasonable cross-section of different types of industries. The result was a list which represented a large cross section of business in the United States.

In Western Europe, the same survey was mailed in France, West Germany, The United Kingdom, and Holland. Mailings in Europe were considerably smaller than in the United States.

4.2. QUESTIONS ON THE SURVEY INSTRUMENT

Data Collection Form Used

LINKAGES TO YOUR **SUPPLIERS**	Purchasing and Manufacturing	Marketing and Sales	Distribution and Service
Business Functions Linked Together			
M-bytes Trans/Month	M-Bytes	M-Bytes	M-Bytes
Linkages Operational How long?	Months	Months	Months
LINKAGES TO YOUR **CUSTOMERS**	Purchasing and Manufacturing	Marketing and Sales	Distribution and Service
Business Functions Linked Together			
M-bytes Trans/Month	M-Bytes	M-Bytes	M-Bytes
Linkages Operational How long?	Months	Months	Months
LINKAGES TO YOUR **STRATEGIC ALLIANCE PARTNERS**	Purchasing and Manufacturing	Marketing and Sales	Distribution and Service
Indicate the type of strategic alliance and company involved			
Business Functions Linked Together			
M-bytes Trans/Month	M-Bytes	M-Bytes	M-Bytes
Linkages Operational How long?	Months	Months	Months

The survey was mailed during the spring and summer of 1990. In some cases, the survey was delivered via facsimile, but these cases were small in number.
As the surveys were returned, the data was organized into two major groups: service companies and manufacturing.

4.3. TELEPHONE INTERVIEWS

Two separate sets of telephone interviews were conducted: Set 1 to follow-up on the survey questionnaires which had been returned; Set 2 to compile case studies of telecommunications planning.

Set 1: Since the returned survey instruments were frequently incomplete, follow-up telephone interviews were conducted to verify the data which had been supplied and also to collect even more information regarding the specific challenges being faced by the various telecommunications organizations.

Set 2: In the second series of telephone interviews, a list of telecommunications managers sampled randomly from a list of the 100 largest telecommunications customers of AT&T was used to make contact. After the telephone interview, we followed up by sending them a copy via facsimile of the survey questionnaire.

Strategic Linkages with Suppliers, Customers and Business Partners

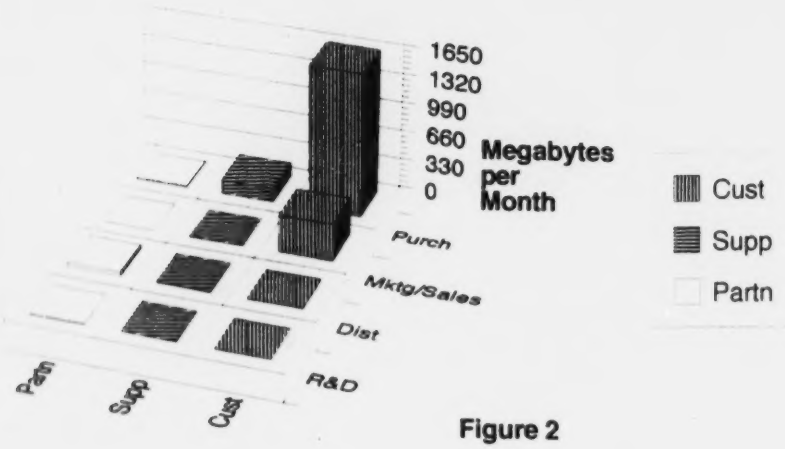

Figure 2

4.4. VERIFICATION OF DATA

The telephone interviews were used to verify the answers which had been returned with the survey questionnaire instrument. This was an important exercise, as there were many minor changes in the data which were required.

In addition, in those cases where the response appeared to be too far out of the expected range, the answers were checked again with the respondee and verified. If the out-of-range number was in fact the case, then the telephone interviewer probed to get some additional insight into how the number came about. This was a most useful exercise in understanding the situation being studied.

4.5. ANALYSIS OF OVERALL RESULTS

After the empirical data had been put together, the general trade press was surveyed to confirm the overall trends which were appearing. In addition, we concentrated on correlating to the fullest extent possible the statistical picture we were receiving against the reality of what we were learning from the case studies.

A reasonableness check was performed on all of the data by matching the conculsions carefully with what different consultants have been experiencing in various assignments. This helped confirm the general trends, and improve the general validity of the conclusions drawn here.

5. STRATEGIC TELECOMMUNICATIONS LINKAGES WITH SUPPLIERS, CUSTOMERS AND BUSINESS PARTNERS

The variety of strategic linkages made between the firm and its customers, suppliers and business partners can be distinguished according to the busines function which is responsible for initiating or managing the linkage.

The data suggests that all three types of linkages are being used perhaps more widely than we would have estimated in the absence of data. However, different functions within the firm are "specialized" in different linkages. Purchasing and manufacturing has the greatest amount of linkages with its suppliers, as one might expect. Marketing and sales has the vast bulk of its linkages going to the customer base, and the distribution and service functions are responsible for most of the inter-organizational linkages. (See Figure 1)

This type of specialization makes sense in light of the respective responsibilities of the different functions involved.

6. STRATEGIC TELECOMMUNICATIONS LINKAGES -- TRAFFIC VOLUME

Measurement of the volume of data being telecommunicated over these linkages yields a slightly different picture. The data shows that although each of the four major functional areas of the firm are maintaining some level of strategic link-

515

STRATEGIC LINKAGES -- NUMBER OF MONTHS OPERATIONAL

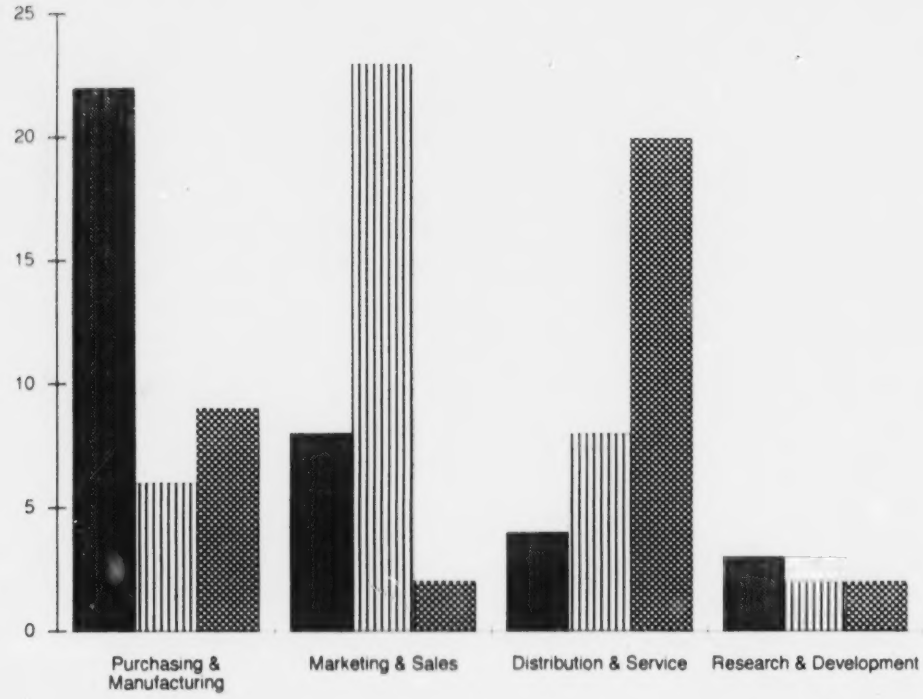

Figure 3

ages, the purchasing and manufacturing function and its linkages to customers represent the greatest volume of transactions by a very great margin. The second greatest category of volume transmission is from the marketing and sales function to the customer base. In terms of the total amount of information being transmitted through these strategic linkages, fully 90% is to the customer. (See Figure 2)

This would suggest that investment in other types of strategic linkages are not as well developed at this point and can benefit from further investment in the future.

7. STRATEGIC TELECOMMUNICATIONS LINKAGES -- HOW LONG HAVE THEY BEEN OPERATIONAL?

An hypothesis that strategic linkages are still in the development stage is supported by the data which examines how long they have been in effect. The data shows that on average companies appear to have strategic linkages which are only approximately 2 years old, for the most mature and widely used linkages; and considerably younger for the other types of linkages under consideration.

Megabytes per Month	Purch & Manuf	Mktg & Sales	Dist & Svce	R & D
To Suppliers	157	1	10	2
To Customers	1,655	426	3	0
To Bus Part	13	1	40	0

The research and development function appears to be at the lowest point in the learning curve for this development; but the other functional areas each appear to be working on exploitation of the technology. (See Figure 3)

8. CONCLUSION: THE NEED FOR "RELATIONSHIP MANAGEMENT" ON THE PART OF TELECOMMUNICATIONS

The key management challenges for the 1990's involve better "relationship management" on the part of telecommunications as it deals with the information systems function, with line management steering committees in the firm, and with parties outside the firm involved in telecommunications-based strategic linkages. The new technologies available, as well as many factors external to the firm (i.e. increased competition), tend to put considerably more pressure against the telecommunications executive. It is a changing picture in which old assumptions about roles and successful behavior patterns must change.

There are several types of relationships which must be managed *simultaneously* in order to effectively create the best telecommunications environment for the firm. The relationship with the information systems function is critical in this effort. Building strategic linkages along the value added chain requires much more teaming than in the past to ensure that telecommunications supports the strategic mission of the firm.

Another area of relationship management concerns the connections which the telecommuncations function may have with organizations *outside* of its own firm. Particularly in the realm of strategic linkages, the telecommunications function is inevitably responsible for keeping the linkages up and running at all times. In most cases, these are critical activities. Due to the very high importance of these linkages, the telecommunications function must emphasize prudent and careful management.

In building alliances with outsiders, the telecommunications function may become the only "face" that others see from the firm. This may in some cases be a considerably higher and more visible profile than the telecommunications function has been accustomed to in the past.

LEGAL AND REGULATORY ASPECTS OF MEDIA INTEGRATION

By Phillip L. Spector
Partner, Goldberg & Spector, Washington, D.C., U.S.A.

Presented at the Pacific Telecommunications Conference
Honolulu, Hawaii, January 1992

ABSTRACT:

As more and more of the world's telecommunications are carried in digital form, regulators, carriers, and end users will face a host of new challenges. In a digital environment, the concept of services -- video, voice, data, etc. -- is no longer meaningful. Rather, all services become binary "bits" in data streams, and carriers become the providers of pipelines for these bitstreams. Because there is no way to distinguish a video bit from a voice bit or a data bit, it will be increasingly difficult for regulators to distinguish video from voice or data services, or to control the content of information transmitted over digital networks. One likely result is more competition, with attendant benefits for telecommunications users.

The transition to an all-digital telecommunications operating environment has important implications for how telecommunications are offered and regulated. This paper explores some of the implications, distinguishing today's services-based model of telecommunications regulation from the emerging "pipeline" model. The paper discusses those legal and regulatory approaches best suited for the dynamism of the current environment and contains a case study of the global satellite marketplace, where many of the legal and regulatory issues involved in digitization have come into sharp focus.

I. THE SERVICES-BASED MODEL

In most countries today, telecommunications are offered and purchased within specific service categories. If one wants to make ordinary telephone calls, he obtains a voice-grade line from the telephone company. While this line may be used for certain kinds of data services -- including particularly facsimile services and computer modem communications -- the line is not intended for data and does not provide the kind of reliability that is typically demanded in data networks.

If a company has major data communications needs, it does not purchase voice lines from the telephone company. Rather, it will purchase special data services, which allow it to send data at speeds considerably faster than it could over conventional voice lines, and with significantly better bit error rates. Similarly, if a company wishes to transmit video, it would typically purchase video services from the communications provider, rather than attempting to make video signals work properly over an ordinary telephone line.

There are many variations on these three (voice, data, and video) themes. For example, Comsat's tariff for U.S. services via Intelsat satellites lists five kinds of voice grade services, some six video alternatives, and four digital services. Within each of these options, the user must make choices regarding such matters as bandwidth, data speed, preemptibility, and term.

From a user's perspective, the availability of so many service alternatives is both good news and bad news. The good news is that most of these services evolved as a result of specific user requests, and hence their availability represents responsiveness on the part of major telecommunications providers, including the governmental and quasi-governmental administrations that dominate global telecommunications. The days are gone when, as AT&T used to be quoted as saying in the United States, you could have any color of telephone you wanted, so long as it were black.

The bad news is that the wide variety of service choices can be confusing, and the distinctions are often arbitrary. In some countries, data sent over leased "private lines" is regulated differently from data sent over "public" networks, even though the same facilities may be used in both cases. And if the service offerings are sometimes more clear, the pricing may not be. Without lawyers, accountants, and other experts -- luxuries that generally can be afforded only by larger users -- it is difficult for the businessman to evaluate which service alternatives best meet his needs.

In terms of legal and contractual relationships, the services-based model plainly advantages the service provider/carrier, rather than the user. The carrier understands its tariffs and is able to tailor service offerings in a manner intended to maximize returns from the carrier's capital investment in a network. When the carrier negotiates with the user, the carrier does so based on its own tariff, and the user generally

has little ability to affect price or offering terms. Even today, when the largest telephone companies are paying more attention than ever to customer responsiveness, and when "custom tariff" deals can be negotiated, the notion of "user friendly" services is still more a matter of public relations hype than it is telecommunications reality.

Governmental regulators, like service providers, find themselves advantaged by the services-based model. In many nations, of course, there is effectively no distinction between the governmental regulator and the telecommunications service provider, although there is a worldwide trend toward separating regulatory and communications provision functions. Even where regulatory functions are separated, there is an advantage for the regulator in dealing with discrete services, because the government may wish to subject different forms of service to different regulatory regimes. Thus, for example, several nations have insisted on maintaining their monopoly over voice services, while allowing a more deregulated, competitive approach to data services. Similarly, for cultural and trade-related reasons, nations may want to exclude certain video programming from other nations, while encouraging for commercial reasons full cross-border information flow with respect to voice and data.

The services-based approach often leads to maintaining telecommunications rates at artificially high levels, thereby discouraging use of the network and assuring inefficient use of plant. For example, prohibitions on resale are common in many tariffs, as part of how services are defined; while nominally intended to "protect" the small user, these prohibitions effectively raise prices, and at the same time prevent the efficiencies that are realized when users are able to share excess capacity. Tariff restrictions relating to connection to the network (except when rigorously justified on technical grounds) similarly do not advance goals relating to the needs of users or the efficient use of the network.

The separation of telecommunications into various services with complicated tariffs thus facilitates economic and technological inefficiencies, while giving regulators more "handles" onto which they may grasp in their efforts to achieve certain social and policy goals. These goals, however, are fundamentally unrelated to telecommunications functions, which can best be achieved when the regulators loosen their grip on, or let go of, many of the handles. It is also the case that, regardless of efficiency considerations or policy goals, governments throughout the world are going to be forced to release more and more of the handles, as digital technologies become dominant in global telecommunications.

II. THE PIPELINE MODEL

To understand the regulatory transition to a digital environment, it is helpful to think of telecommunications in terms of a grouping of pipes, rather than a grouping of services. Just as would be the case in a municipal water system, the pipes are of various sizes and have different technical qualities, with larger pipes going down main arteries and smaller pipes branching off to individual businesses and homes. As with the water system, moreover, the substance flowing through these telecommunications pipes is in all cases essentially the same: the digital bits that make up the essence of modern communications.

To continue the metaphor, different nations, and even different areas of the same nation (especially urban vs. rural areas), are in quite different stages of development with respect to this key component of infrastructure. Some are still using the communications equivalent of the backyard well, while others are in the process of laying fiber -- fundamental to any serious digital system -- to every home and business. Obviously, the nations with more backward systems will have strong incentives to modernize, or to encourage private industry to do so, in order to remain competitive in the global economy.

The legal and regulatory implications of the transition from a services-based model to a pipeline model are enormous, and are only just beginning to be understood. From a contractual standpoint, in terms of the relationship between the service provider and the user, the advantage in the pipeline model goes to the user. The bargaining is not over confusing service options, carried out in the context of a tariff dictated by the service provider, but rather is based simply on determining which characteristics of the pipe (e.g., size, transmission medium, bit error rate) are most important to the user, and how much the user is willing to pay for them. Because the pipes providing telecommunications are often fungible, moreover, the user is in a position to shop around for the best deal, assuming that the regulatory authorities will allow competition.

Regardless of whether telecommunications pipelines are offered monopolistically or competitively, there will be an increasing need in the future for providers of value-added services and equipment. As more countries are recognizing, it is advantageous to encourage vigorous competition in these areas, because such competition leads to more use of the basic network. Only the largest users have the in-house sophistication necessary to take advantage of the flexibility offered by digital pipelines. For smaller users, intermediaries in the form of value-added service providers and equipment vendors are vital, serving to make modern digital communications accessible to all.

This accessibility, however, is dependent on the pipelines being available, and at reasonable

prices. Neither availability nor reasonable pricing can be assured in the absence of competition in basic services. In a monopoly administration, where a single provider makes the infrastructure investment decisions, and where pricing of the pipeline is typically well above cost, value-added networks ("VANs") are not likely to flourish, and telecommunications modernization will be slowed as a result. There is thus a direct and inescapable relationship between a nation's encouragement of VANs and its willingness to allow competition in the provision of communications pipelines.

As telecommunications comes to be seen in terms of pipelines, rather than services, and as digitization and media integration become commonplace around the globe, regulatory authorities will have little choice but to allow more competition. When users are purchasing undifferentiated pipes, it becomes difficult, and often impossible, to determine what kinds of traffic are being carried over networks. Digital voice, data, and video simply cannot be distinguished, and regulatory structures based on such distinctions will look increasingly anachronistic. As the pace of digitization accelerates, moreover, complicated communications service categories, and the government bureaucracies necessary to keep track of those categories, will no longer be justifiable, and many of the non-telecommunications goals served by regulation will not be capable of achievement.

Government might still be able to maintain a monopoly provider of the basic pipeline, but it is reasonable to ask why government would wish to do so. When telecommunications is viewed as a relatively fungible commodity -- a stream of bits proceeding down a pipe -- there would seem to be little justification for monopoly treatment. Why should other commodities be sold in competitive markets, while data bitstreams are restricted to monopoly provision?

One answer commonly given is that there is a public interest in a universal, ubiquitous telecommunications infrastructure, serving rich and poor, urban and rural areas alike. Competition, the argument goes, leads to "cream-skimming," with the heavy traffic areas well served while the "thin routes" are not served at all. This argument, of course, is simply one for cross-subsidization -- i.e., charging higher rates in some areas in order to underwrite service to other areas.

In fact, however, subsidization is going to become increasingly difficult to sustain, as digital networks encourage (and make virtually undetectable) bypass of public switched facilities -- particularly if the rates for public facilities are kept artificially high. Thus, for example, a government that has determined to deregulate all areas except switched voice may quickly find that its proclamations are essentially being ignored by at least the larger, more sophisticated users, who will have no difficulty mixing voice and data over their digital pipelines, and who will have strong incentives to do so. Any private line that terminates at a PBX instantly becomes a means of entry into the public network, bypassing elaborate regulatory mechanisms and remaining all but undetectable to the regulators. Similarly, while video program control may be maintained at the consumer level (e.g., through broadcast and cable television regulation), there will be substantial quantities of video material that will enter the country as digital information (e.g., via satellite) that cannot easily be controlled by government.

If social goals relating to rural infrastructure are to be achieved, such goals should be addressed directly (e.g., through taxes or user fees), rather than in ways that distort use of the network and create other inefficiencies. It is also the case that competitive markets respond to user needs, even in thin route situations, developing creative technological solutions in the absence of massive government subsidies. For example, rural telephone networks are increasingly being implemented based on satellite and radio communications, rather than on the highly inefficient stringing of telephone lines to remote areas.

Trends unrelated to digital technology, including especially the globalization of trade and the breaking down of national barriers, should help to accelerate the movement toward competitive digital networks. In a Europe in which, within a few years, national boundaries may be relevant solely for linguistic and historical purposes, it will no longer be acceptable for national telecommunications administrations to impose differing service definitions and differing technical standards for interconnection to the public network. Instead, Europe is moving toward diverse and competitive digital networks, with open architecture accessible to a wide range of equipment vendors and enhanced service providers.

Digital technology and the move toward media integration will impact dramatically on the legal and regulatory structures of telecommunications that have been built up over the past century. Some governments will undoubtedly resist the forces of change, and insist for years to come on maintaining monopoly administrations focused on outdated concepts of voice, video, and data services. Ultimately, however, economic development will be retarded in those nations that resist too strenuously, and even the holdouts will come to embrace the reality of digital pipelines and the accompanying advantages of competition.

III. THE COMMUNICATIONS SATELLITE MARKETPLACE: A CASE STUDY

Developments in digital communications are typically associated with developments in fiber optics, because the fiber optic medium is

entirely digital. If satellites are thought of at all in this context, it is almost as an afterthought -- i.e., satellites too can provide digital communications. In fact, satellites are increasingly part of digital networks, being used not only for data services, but also for digitized video (particularly when compression of signals is a factor) and digitized voice.

The media integration trends discussed in the preceding sections raise interesting regulatory issues in the context of satellites. Satellite communications are inherently difficult for regulators to control; satellites cover wide areas and do not respect national boundaries. Thus, for example, a homeowner with a small receiving dish may pick up television programs not only from his home country, but from neighboring countries as well -- a situation with which governments in Europe and Asia are increasingly familiar.

These difficulties will be exacerbated by the likely growth in digital transmissions by satellite. If government regulators are seeking to keep out certain television programs, but at the same time welcome the reception of financial information, their efforts will be substantially complicated by satellite television's likely transmission in digital, compressed form within the next few years. Similarly, proposals to deliver compact disc-quality audio via satellite to small dishes at homes (and even in moving cars) raise issues about content control; such CD transmissions will be nothing more than a stream of data bits, indistinguishable from voice or data communications except by configuration. Indeed, some of the satellite CD audio proposals would use the same equipment for digital messaging (e.g., paging) and other forms of communication.

The situation facing governments as they attempt to regulate private international satellite systems offers another illustration of the regulatory dilemmas. These satellite systems have been restricted, in order to protect Intelsat, to the provision of services "not interconnected with public switched networks." This restriction, known as the "PSN restriction" in the United States, seemed relatively simple to enforce when it was adopted in 1985, at a time when communications traffic could be divided cleanly among public switched and private line networks.

As digital communications have come increasingly to be the norm, however, the public/private distinction has become far less meaningful. When satellite communications for large users are provided primarily on a pipeline basis, as is the case on satellite systems that sell or lease transponders, it is unduly restrictive to say that that pipeline cannot be connected, at either end, to public switched networks. Large users want "seamless" networks of voice, video, and data, linking private lines with public networks around the world; they are not willing artificially to segregate their traffic to meet a government regulation that cannot be justified on efficiency grounds. If the United States and other nations insist on maintaining an artificial distinction between public and private international satellite networks, the end result will be to drive large users away from satellites altogether.

By making satellites more expensive to use, therefore, the U.S. PSN restriction promotes use of undersea cables for international communications, thereby ironically undermining the restriction's key goal -- the protection of Intelsat's PSN traffic base. These kinds of unintended consequences are likely to multiply in a world in which undifferentiated bits of data move freely among public and private, switched and nonswitched networks, domestic and international. In such a world, moreover, any attempt to enforce restrictions on PSN interconnection will ultimately be frustrating -- and a poor use of limited regulatory resources. (The author is counsel to Alpha Lyracom/Pan American Satellite, which is actively seeking elimination of the U.S. PSN restriction.)

A similar point applies to the discussion in many countries about the relative advantages of teleports versus on-premises small earth stations (often known as "VSATs") for satellite transmission and reception. To the extent that governments seek to maintain their control over monopoly communications, teleports may be a preferred solution, because they concentrate incoming and outgoing communications at a single point. From a user's perspective, however, teleports are one solution, with customer-premise earth stations being another; the choice should be made on the basis of quality and price considerations, not on the basis of regulatory fiat. Experience in the United States has demonstrated that, at least when the satellite marketplace itself is robust, there will develop a mix of teleport and customer-premises solutions, giving users the flexibility to configure their networks to meet their service needs.

In areas relating to satellite communications, then, the emerging digital networks are likely to bolster the argument for less regulation and more

freedom of choice. Because governments will no longer find it easy to differentiate among the various forms of satellite communications -- voice, video, data, switched, nonswitched -- they will find it necessary to opt for less regulation overall, leaving the satellite marketplace to work in a competitive manner.

IV. THE FUTURE OF MEDIA INTEGRATION AND REGULATION

As communications media come to be represented by digital bitstreams, the function of the regulator should be much reduced. As discussed above, pipeline offerings are neither complex nor threatening to the public interest. Rather, these offerings involve fungible commodities, and in such situations government works best when it steps back and allows the market to operate.

The notion of an open market in digital communications is not necessarily inconsistent with maintaining a role for monopoly administrations, in those countries that choose this approach. Even if the monopoly is limited to providing the basic digital pipelines, however, large users, equipment vendors, and value-added service providers will not be able to develop competitive and innovative uses of the pipelines when constrained by the pricing practices and investment decisions of the monopoly. A monopoly approach is also not well suited to the realities of cross-border satellite communications and cannot fully take advantage of the commercial and entertainment opportunities presented by this increasingly digital medium.

All communications regulators, in monopoly and multicarrier countries alike, should be prepared for the transition to what this paper has called the pipeline model. Digital communications will be increasingly the norm, and the traditional lines drawn among communications services will come to seem increasingly irrelevant. In nations where this media integration process is welcomed, rather than resisted, members of the public will be the ultimate beneficiaries, receiving better quality services at lower prices.

LOUTCH 1 - THE ESTABLISHMENT AND OPERATION OF A MOSCOW/LONDON SATELLITE LINK

Christopher Pooley, AMIEE
BrightStar Communications Limited
London, United Kingdom

This paper discusses some aspects of the regulatory, political and commercial environment of the European satellite business. In particular, it gives a practical account of the establishment of an Intersputnik satellite link between Moscow and London, and its integration into a global satellite network.

1. INTRODUCTION

Visnews is a global television news agency - the largest of its kind, and has made use of satellites for news gathering and distribution since video transmissions were first made possible in the early 1960s. [1]

With over 30 regular daily feeds around the world [2] satellites are now fundamental to the Agency's business. It was against this background, in 1983, that Visnews established its subsidiary, BrightStar Communications, to operate the first private transatlantic TV transponder lease and to service its own satellite needs, as well as those of other broadcasters on a commercial basis.

Following the demand for increasingly fast relay of news and sports programming, the BrightStar satellite system grew from one reversible channel to the current three transatlantic channels on Intelsat at 332.5° East. These interconnect via network operating centres in the east with a channel on Eutelsat II-F1 and another on Gorizont 30 (Statsionar 4), and in the west with a full-time channel on a US domestic satellite [3].

The system is also connected on a daily basis to various Pacific leases to feed the Western Pacific Rim. Thus it provides a "seamless" transmission route embracing most of the world from Moscow through London, Washington and LA to Tokyo.

The development of BrightStar has been driven by market forces in the television industry and the demand of users for simpler, more reliable links. But it also runs parallel with the gradual deregulation of satellite communications in different regions. The first stage took advantage of the US "Open Skies" policy; the most recent stage - the integration of a Moscow-London Link into the system - of a combination of liberalization in Europe and *perestroika* in the Soviet Union.

"Seamless" television communications have not come about easily and many compromises are still being made. The following case history charts that progress in the context of the regulatory, political and commercial environment of Europe.

2. THE PROGRESS OF DEREGULATION IN EUROPE

One of the main obstacles to the expansion of commercial satellite communications in Europe has been the regulatory environment. Only five years ago, European Telecom Organizations (TOs) had a complete monopoly of the linking of TV signals into, out of and around Europe. The only exception to this was the terrestrial closed user "Eurovision" network of the European Broadcasting Union (EBU).

At that time, in the United States, BrightStar had built co-located earth stations to connect international and US domestic satellites in order to bypass the complex routing of signals via long lines to existing switching centres [4]. By contrast, in the UK, transmissions had to be made via costly terrestrial lines to British Telecom's 30 metre international earth station on the west coast of England. No other European TO would uplink direct to BrightStar transponders.

European broadcasters wishing to use BrightStar were able to do so only by virtue of a special arrangement made with the EBU, enabling their members' material to be sent to the London Operating Centre on the Eurovision network.

This was a period when the traditional monopoly of the European national public service broadcaster was ending, and new TV stations in an increasingly competitive market were demanding better access to communications facilities.

For links between Europe and North America for non-EBU members BrightStar had two alternatives - use of Intelsat ad hoc capacity or landlines. Landlines were expensive, unreliable and re-routable in some countries, so the cost of a transmission was not known until the route had been fixed which, quite often, was not until just before the event.

The complications of routing transmissions were immense and costly, even in the UK. BrightStar was at the mercy of any increased lease charges which British Telecom chose to impose. But BrightStar's objective was to relieve broadcaster customers of worry and provide efficient links for a single, known price. This relatively simple expedient so revolutionized newsgathering operations that demand for the service increased the total amount of television traffic across the Atlantic, and made the UK an important communications centre [5].

By 1988, the introduction of 13 metre earth stations meant that transmissions could be made direct from city teleports, thus reducing the need for long-distance landlines. At that time, anxious about the UK's prominence as a television communications centre, the TOs of Germany and France (Deutsche Bundespost and

323

France Telecom) reached agreement with BrightStar to uplink to its Atlantic leases from fixed earth stations in Frankfurt and Paris.

In that year, the rules on downlinking were relaxed in most European countries to permit the reception of satellite delivered television channels. The exceptions were France, Italy and Spain, although Telespazio and Telefonica did agree to uplink to BrightStar space segment from their own transportable earth stations.

The next step was for the Deutsche Bundespost and British Telecom to allow access on the same terms. The introduction of Ku-band capacity on Intelsat Atlantic had made direct uplinking from Europe highly desirable - particularly in view of a burgeoning market for live sports programming transmissions.

The apparent relaxations in the regulatory situation at this stage did not, by any means, apply universally. BrightStar was the only private international leaseholder with "common carrier" status in existence and each uplinking agreement with each country was negotiated individually, and applied only to BrightStar.

The feeling in the industry was that, as the process of deregulation and harmonization gained momentum towards the European Single Market in 1992, the different regulations existing from country to country would gradually be removed. But it was reckoning without the immense economic power and lobbying might of the Telecom Organizations - many of which were governed by ancient statutes giving them control over post, telephone and telegram systems in perpetuity. It would require considerable political will within each member country to alter the status quo.

The subject of European Telecommunications liberalization was addressed in a Green Paper by the European Commission in 1987 - but Satellite Communications were not included. This was to be tackled in a separate document scheduled for 1989.

The satellite communications Green Paper, entitled "Towards Europe-wide Systems and Services" [6] was not published until November 1990, due to an effective action fought by the French, Italian and Spanish TOs. Meanwhile the UK and Germany were working on national deregulation policies ahead of European directives, and these provided the impetus for BrightStar's subsequent development.

3. UNITED KINGDOM REGULATORY HISTORY

In the UK, the process of telecommunications deregulation began early, and satellite communications were first allowed limited private operation in November 1988.

Six Special Satellite Service Operators (SSSOs) were granted licences by the Department of Trade and Industry to offer a range of commercial television and data services: SIS, Maxwell Satellite Communications, British Aerospace, EDS, BSB, and Uplink (later acquired by Reuters and operated by BrightStar)

The licences entitled the licensees to uplink within the UK from up to three uplinks simultaneously and to downlink to any number of receivers for end use only. This meant that signals could not be relayed again from the point of reception and interconnection with the Public Switching network was not allowed. [7]

British Telecom had had a major influence on the terms of these licences, which were so limiting as to be of little practical use in commercial terms. As a result the DTI, which had a genuine desire to see satellite services develop, extended the SSSO licence in 1989 technically to include continental Europe, and in January 1990 a Class Broadcaster Downlink licence was announced which granted permission to certain entities, including BrightStar, to downlink TV signals from *"any orbiting apparatus"*. This was to be a phrase of crucial importance to BrightStar in the near future.

The new licence enabled BrightStar to downlink and onpass any TV signal and to uplink to any European satellite. Visnews European newsgathering and distribution requirements were growing at a fast pace - particularly since there were now some 40 new television stations in existence in Europe who had no access to the EBU's European (and by now also transatlantic) communications infrastructure and news exchange system. Less highly-resourced than the national broadcasters, the new stations were keen to exchange programming between themselves as well as to share transmissions from further away. The time was right for Visnews and BrightStar to lease a European transponder.[8]

The full-time channel, on Eutelsat II-F1 came into the system on 1 January 1991. It is a powerful satellite with a wide uplink footprint covering east and west Europe, Scandinavia and parts of the Middle East; ideal for satellite newsgathering (SNG) using a 1.9 metre transportable earth station. Its superbeam downlink coverage allows reception on dishes as small as 90 centimetres - although BrightStar recommends a slightly larger receiver if the signal is to be processed and re-broadcast.

Visnews set up an important European news and communications system for its customers on the satellite called VisEurope. It was fully utilized during the Gulf War and has been supremely useful for coverage of all major news and sporting events since, many of them in real time.

In August 1991, the DTI issued the UK Satellite Services Class Licence which permits uplinks to any satellite subject only to earth station approval and licensing by the Radio Agency [7]. For BrightStar, with its European network hub in London, this was the final earth segment barrier removed, allowing it to uplink direct to intercontinental satellites - and its own transatlantic leases in particular - for the first time.

With the exception of Germany, the UK regulatory position is the most advanced in Europe, but some aspects still remain to be resolved. The most important of these is right of access to space segment providers.

Ironically, direct access to private space segment providers, such as SES or Alpha Lyracom, is permitted, but the purchase of capacity on Eutelsat or Intelsat satellites must be done through the National Signatory which, in the case of the UK, is British Telecom - the main competitor of any UK private satellite service operator. [9]

In a bid to solve this problem, a separate Signatory Affairs Office (SAO) has been set up within BT but with

a notional Chinese Wall between it and BT's commercial operations. The price of Intelsat and Eutelsat space segment ordered though the SAO is yet to be decided, as there is a suggestion that significant users of space should contribute to the capital investment of the satellite consortia in proportion to their usage. There are some estimates which suggest that this could involve a 10-40% mark-up on the current satellite consortia price of a transponder.

This situation would obviously discourage buyers from using the SAO and drive them into the arms of BT or other private satellite operators. The industry ombudsman - the Office of Telecommunications (OFTEL) will eventually rule on the matter, but for the time being the position is confused and very unsatisfactory.

4. THE CURRENT REGULATORY ENVIRONMENT IN EUROPE

Access to space segment providers is a problem which exists throughout Europe, largely because Eutelsat is an organization which is governed by treaty - in the same way as the European Community - and it is larger in terms of member countries (28 in total) than the European Community itself (12 member countries). Thus the European Community's administration, the Commission, has no power of enforcement over the recommendations it makes to Eutelsat. The consortium is collectively owned, not by countries per se, but by Telecom Organizations, some of which are no longer state controlled.

In most countries there are still major blocks on the use of the earth segment too [10]. Uplinking is mainly still the prerogative of the national TO and downlinking is either officially deregulated or unofficially tolerated. The situation is further complicated in some countries where separate organizations control satellites and landlines, thus presenting two bureaucratic hurdles. Even TOs which allow uplinking to leased transponder time retain a total monopoly of access to ad hoc capacity.

The 1990 Green Paper on a common approach to satellite communications in the European Community proposed four main changes to policy:

1. Full liberalization of the earth segment including both receive-only and transmit/receive terminals subject only to type approval

2. Unrestricted access to space capacity

3. Full commercial freedom of space segment providers including direct marketing of satellite capacity to service providers and users

   (1-3 would be subject to licensing procedures)

4. Harmonization measures as far as required to facilitate the provisions of Europe wide services.

More recently - November 1991 - the EC Council of Telecommunications Ministers endorsed some of the recommendations of the Green Paper and invited the European Commission to propose measures to achieve the goals, in particular:

a. to extend the principles of the Commission Directive of 16 May 1988 on competition in markets for telecommunication terminal equipment and services to existing satellite earth stations by 1 January 1993

b. to reconcile the laws of Member States concerning existing earth stations, including the mutual recognition of standards, on the basis of the principles already established for telecommunication terminal equipment, by 1 January 1993

c. to establish a harmonized regulatory framework for satellite networks and services by 1 January 1993

d. to reinforce co-operation with CEPT according to the principles of the Council Resolution of 28 June 1990 concerning frequencies for the provision of satellite services within the Community

e. to guarantee free circulation and transborder use of mobile and transportable satellite earth stations throughout the Community by 1 January 1993

f. to establish non-discriminatory, accelerated procedures for the establishment of separate satellite systems

g. to improve and widen access to the space segments of intergovernmental organizations - taking account of special or exclusive rights for the provision of public telecommunications services.

On first reading this looks very promising, but in practice two points must be remarked: Firstly, notice the subtle difference between point 2 of the original proposal - *"unrestricted access to space segment providers"* and point g, *"to improve and widen access to the space segments of intergovernmental organizations"*. This means that private satellite service operators will continue to have to approach Eutelsat and Intelsat through the intermediary of each member state's National Signatory - with no alleviation of the attendant surcharges which can add up to 70% to the cost of a lease.

Secondly, the mills of Community administration grind exceeding slow by commercial standards. Bearing in mind that it took two years to produce the original proposals and a further year for their endorsement by the Council of Ministers, the next stage will be the wording of 'Directives' by 1st of January 1993, and it will probably take a further year before legislation reaches the statute books. It will therefore be 1995 before any of these freedoms are enforceable under European law. In the meantime, private satellite service operators will have to rely on the political will of national Ministries to see liberalization progress in their own countries, and the goodwill of national TOs to respect the intent.

I have mentioned previously that national TOs in Europe wield considerable power. In the present transitional phase of deregulation, they are not above tactical rule-making to inhibit competition even when national policy is liberalized.

Germany was the first country in Europe to instigate a genuinely liberal environment designed to encourage private satellite service operators providing both television and data services. This took the form of a Class Licence which was announced in 1990, before the Green Paper, whereby for the payment of a moderate licence fee, uplinking could be carried out by any competent organization.

Recently, however, there has been a sudden reversion to monopolistic practices by Deutsche Bundespost Telekom, acting unilaterally without the sanction of the Telecommunications Ministry. In November 1991, Deutsche Telekom imposed without notice ruling that restricted access from Germany to German space capacity only. BrightStar, on the eve of a transmission contract involving some 50 hours of sports programming feeds for various clients booked on its own space capacity, was the victim.

The only solution acceptable to DBP Telekom was a lease-back and re-lease procedure [11], that is BrightStar returned its capacity to Eutelsat, who in turn leased it to DBP Telekom, who re-sold it to BrightStar with a 33% surcharge. This procedure resulted in a loss to BrightStar of many thousands of pounds. In spite of pressure from the German Ministry of Telecommunications, the European Commission, and even from Eutelsat, the situation continued and is now subject to legal review (at November 1991).

This demonstrates that, to be a private satellite services operator in Europe, it is wise never to make assumptions, and always to anticipate a 'worst case' scenario. Fortunately, as an engineer this comes easily to me. It is much harder for the people in sales and marketing to swallow.

By contrast to the German experience, British Telecom is so far abiding by UK law [7]. Indeed, the 1990 Class Broadcaster Downlink Licence proved to be the spur for the next stage in the development of the BrightStar system.

5. THE MOSCOW CONNEXION

As events in Eastern Europe concentrated news attention on Moscow, Visnews and BrightStar were keen to improve transmission links with that region. Investigations showed that the phrase in the Class Downlink Licence allowing the downlinking and onpassing of signals from *"any orbiting apparatus"*, included the Intersputnik system. So in March 1990, BrightStar approached Intersputnik about the possibility of using a Ku transponder on one of its satellites. Thanks to *perestroika*, Intersputnik responded enthusiastically to the idea [12]. Agreement was quickly reached for one hour per day on the Loutch transponder on Gorizont Statsionar 4, transmitted from Moscow and received in London on a transportable terminal until a permanent TVRO could be installed. Service began, appropriately, on 23rd April - St George's Day (patron saint of England and the city of Moscow).

There are said to be three things that work in Moscow - the Metro, the heating and the snow clearance. BrightStar found a fourth - Intersputnik! However, the bureaucracy, uncertainty and lack of hard currency makes everything else very difficult. All materials down to nails and screws have to be imported!

Microwave links in Moscow are very expensive and cost the same whether the equipment is self-provided or not. As lack of hard currency prevents the TO from importing microwave equipment, there is little alternative to self-provision.

Intersputnik has a considerable stock of satellites [13]. It will be noted that the Statsionar number refers to the orbital slot; Gorizont is the satellite type and Loutch is the Ku transponder on a Gorizont satellite.

There are one or two difficulties in using the Gorizont satellite - one is that the signal is of circular polarization and the other is that the satellite is in inclined orbit. In choosing its permanent receive earth station for the link, BrightStar decided upon a linearly polarized 4.5 metre Scientific Atlanta TVRO with automatic tracking. This allowed its use also as a receiver for other western satellites and it came into operation in October 1990. As there is only one Ku transponder on the satellite, the only disadvantage was a 3dB loss of signal.

The present routing of the signal is from the joint Visnews/NBC/BrightStar offices in Gruzinsky Pereulok (premises are also hard to come by in Moscow), by microwave to the Ostankino tower and then by microwave to the 11 metre uplink at Dubna earth station north of the city.

From there, signals are received at BrightStar's Network Control Centre in London, from where they can be relayed instantly on other parts of the Network, or on other satellite systems [3].

6. AUGUST 1991

Having operated the Moscow-London link for a year with an excellent response from Visnews' and BrightStar customers, it was decided to increase the commitment on Loutch to nine hours a day. When the formalities had been resolved, BrightStar had the choice of starting the service at the end of July or the end of August.

The end of August was favoured as, in the words of journalists in the know: *"nothing ever happens in Moscow in August"*, but as the Moscow Summit was scheduled for the end of July, a start date of 27th July was fixed. Thus BrightStar's expanded operation was ready for the abortive Kremlin coup during which up to 150 transmissions a day were fed out of the Moscow operating centre, beginning with the first television pictures out of Red Square.

Transmissions were relayed without pause from London throughout Europe via Eutelsat II-F1, and via BrightStar's transatlantic link to North America and on to the Pacific - thus providing continuous, almost world wide distribution.

7. THE FUTURE

In as much as it is possible to make firm plans, rather than to declare intentions, for the future in the satellite services business, BrightStar is presently working on a number of improvements to the structure of the network.

The earliest of these is a move and expansion of the transatlantic sector to four channels on the new Intelsat K satellite in June 1992 [14], with a view to incorporating South America into the service, and of improving flexibility for uplinking and multi-downlinking. The all-Ku satellite lends itself, like Eutelsat II, to the use of lightweight transportable earth stations. It is also suitable for roof-top reception on small TVROs - a factor increasingly demanded by broadcasters and business television users who have their own receiving equipment.

There are also plans to expand operations on the Pacific sector, and various options on the Indian Ocean region are being studied.

In Europe, many opportunities exist pending improvements to the regulatory environment, and

BrightStar's role will for some time be in lobbying to this end. We would like to see regulations in whole regions harmonized along the lines recommended in the European Commission's Green Paper. Television and ad hoc television is very labour intensive and, in it's history, BrightStar has continued to build a myriad of small users of satellites up to the level where they take their own leases, at which time they have become direct customers of the TOs and the space segment providers.

There is sufficient commercial risk in the satellite services business without the added disadvantage of impediments imposed by TOs and others taking advantage of their dominant status. As BrightStar and similar organizations provide the software to build the market, it is in the general interest that they be able to continue that work unhindered.

Korea's Experiences in Telecommunications

by

Yong Son

Sang-Chul Lee

De-Ryong Lyi

Young-Ho Ju

Chung-Ang University

Seoul, Korea

Abstract

As Korea ushered into an era for one telephone per household with 10 million telephone lines installed in 1987, the function of telephone was not limited to the voice transmission but further extended to the various value-added services. In an effort to facilitate the extended communication and information services, Korea plans not only to launch its own satellite by 1995 but to install a fiber-optical cable network from 1992. Using this kind of technologies, Korea plans to integrate the various information and communication services into a single network system like ISDN.

I. Background

The telecommunications in Korea has experienced a rapid development both quantitatively and qualitatively in a comparatively short period of time since the first telephone line was installed between Seoul and Inchon, 35km apart.

As Korea ushered in an era for one telephone per household with 10 million telephone lines installed in 1987, the function of telephone was not limited to the voice transmission but further extended to the various value-added services. Korea began data transmission service over telephone in 1983. Accordingly, the information sector loomed very significant in industry, comprising 7.4% in the growth national product (GNP) with $17.7 billion in 1990. The telecommunications part composed 34.5% with $6.09 billion in the information sector.[1]

In an attempt to meet the ever increasing demand of telecommunications, Korea plans to launch its own satellite by 1995. The planned satellite system is geared both for the transmission and broadcasting. Korea designated a foreign company to manufacture the sattllite in December 1991. The planned satellite, called the KOREASAT will include 12 circuits for transmission as well as three circuits for broadcasting. Korea plans to domestically manufacture the satellite system by 2000.

The telecommunications sector, including the planned satellite system, shows the various and significant aspects both in the fields of business and technology.

First, from a point of business, there is a great demand for the mobile transmission and communication. To meet this demand, the licensing will be open to competition. The international telephone service, traditionally monopolized by Korea Telecom, will compete with DACOM(Data Corporation) as the Korean Government allowed the latter to join this service in December 1991. In the meantime, the videotex service, formerly monopolized by DACOM, was allowed to compete with Korea Telecom. Accordingly, Korea Telecom launched a videotex service, called the HiTel, from July 1991, covering 10,000 households in three major areas: Yuiedo in Seoul, Kwachon in Kyunggi Province and Kwangju City.

Second, viewed from a technological point, Korea Telecom plans to complete the optical fiber system by 2006, beginning its work in 1992. Meanwhile, ETRI (Electronics and Telecommunications Research Institute) plans to jointly develop a multi-media system along with other private firms. The metropolitan newspapers have recently installed the nation-wide fax network called 'fax press' to simultaneously print their newspapers in various parts of the country. Korea also started a demonstration service for ISDN from October 1991, covering five hundred households in three major areas, including Seoul. The commercial service for ISDN will start in 1994.

Ultimately, Korea hopes to integrate the various information and communication services into a single system like ISDN.

Under this backdrop, this paper intends to specifically focus on three research questions as follows:

1. this paper will examine the process and prospect for the planned satellite system and the possibility of its linkage to other media systems.

2. this paper intends to look the Korean videotex plan, including the HiTEL sponsored by the Korea Telecom.

3. this paper will examine the relevant issues to better develop the planned ISDN system.

Ⅱ. The Satellite Project

The satellite service began in Korea in 1970 when the nation had installed the first earth station at Keum-san. Korea became a member of the Intelsat in 1967. Korea was allocated the six satellite channels and a slot for the satellite at 116 degrees East on the equator line at the WARC conventions in 1977 and 1979.

The Korea Advanced Institute of Science and Technology (KAIST) did a feasibility study towards introducing the satellite system in 1984. The study designated the period of 1987-1991 as a preliminary stage to complete a blueprint to introduce the satellite system.[2]

According to this blueprint, Korea Telecom, the satellite project organizer, held a briefing session about the project in February 1991 for about 60 representatives from the 27 prospective bidders. The $450 million satellite project, dubbed KOREASAT, will have the capacity for 3,900 voice circuits, three television broadcasting channels and four video channels.

Among the 27 bidding corporations were 17 foreign companies; they included Hughes Aircraft, TRW, General Dynamics, GE and McDonnell Douglas of the United States, Aerospatiale of France, British Aerospace of Britain, MBB of Germany, and NEC and Mitsubish of Japan.

Korea Telecom announced two preliminary consorsium bidders in October 1991--General Electric of the United States with the domestic Lucky Gold Star and British Aerospace of Britain with the domestic Daewoo Corporation. The winner for the project was finally

announced in December 1991 out of the two bidders as General Electronic associated with domestic Lucky Gold Star. The selection was based on the willingness to hand over the core technology.[3]

Based on this initial satellite project, the Korea satellite program will proceed at three stages in the future.[4]

The first period (1992-1995) will be focused on the preliminarily demonstration service. Korea Telecom plans to lease a transponder from the Intelsat-VA in operation to demonstrably offer the satellite communication service. It will also try to build a base towards achieving the first generation KOREASAT business venture. Among the available services during this period will be the transmission service for tele-conference, data & video transmission service.

The second period (1995-2005) is an operational business service stage for KOREASAT. Korea Telecom plans to launch its own satellite through which the broadcasting and the various data services will be available. To support this project, Korea Telecom plans to build the satellite control system, composed of Satellite Control Center (SCC) and two auxiliary control sub-systems.

The third period (after 2005) is a stage during which Korea plans to domestically manufacture the satellite system based on the technology transfer and accumulation during the second stage.

Among the notable things in this project is the linkage of satellite project to broadcasting. The propect of this linkage was expressed by the Minister of Information when he met the mid-career broadcasters in July 1991. In this briefing session, the Minister of Information disclosed a plan to include three DBS channels and four video-transmission channels in the satellite to be launched in 1995. Korea Broadcasting System (KBS) in under instruction to study using these channels.[5]

This kind of linkable plan seems significant as the nation ushers into an era for multi media and broadcasting systems as well as the nation is supposed to focus on the broadcasting structure to face up to the unification between North and South Korea in the 21st century. The introduction of satellite seems vital when the nation is developing HDTV. The satellite system is to integrate the various broadcasting services—the tradition broadcasting, CATV and HDTV.

Ⅲ. The Situation and Prospect of Videotex

The videotex plan was made in Korea in 1982. DACOM was responsible for the early stage of development. However, some metropolitan newspapers, especially economic dailies, and service companies joined this project to diversify its services. In addition, Korea Telecom started to demonstrate videotex service from July 1991, mentioned elsewhere. This service covers 10,000 households in three different places across the nation—Yuiedo in Seoul, Kwachon in Kyunggi Province and Kwangju city. In the meantime, KBS and MBC began teletex services respectively.

DACOM began the videotex service in 1985. The number of user has showed a steady growth—249 in 1986, 612 in 1987, 1,717 in 1988, 5,325 in 1989, and 6,400 in 1990. The growth of this kind is obviously related to the increasing penetration of PCs.[6]

DACOM is currently the largest data bank for this kind of service with 700,000 bits of data in 70 kinds, including 42 kinds of daily life.

The videotex service in France has been a model case especially applied to the positive public service.

Korea Telecom started the videotex service, dubbed HiTEL, in 1991, modeled on the France case. In addition, the introduction of videotex service by Korea Telecom seems to indicate that KT is going to transform the current telephone service into a computer and communication service.

The KT-sponsored videotex service plans to develop its services as follows.[7]

First, KT plans to provide 450 kinds of data service as an initial stage from 1991, including telephone directory, daily life information, educational and medical information. This kind of data services will be based on data bank, developed by KT itself as well as data bank separatively developed by some daily newspapers and DACOM.

Second, KT plans to install PSDN for data service only, fax network for fax service only, CSDN for switching the telephone network into the information network, and HDDN for ultra-speed transmission of mass information. Ultimately, KT plans to integrate this kind of individual networks into a single network, called ISDN.

Korea Telecom plans to invest 1,500 billion Won ($20 billion) by 1996 for this project. Included in this fund are 660 billion Won($880 million) for supply of PCs, 160 billion Won($213 million) for transmission network, 160 billion Won($213 million) for data base, and 47 billion Won($62 million) for voice transmission.

The participation by KT, therefore, is likely to accelerate not only the videotex service but expand the transmission network.

IV. The Plan and Subjects of ISDN

The building of a ISDN is not only a core area of the future information and communication policy but a significant part in its utility of service area.

Korea has formulated a gradual policy since 1984 towards building a ISDN network system. According to this plan, Korea designated the period of 1984-1991 as a preliminary stage during which the digitization of transmission network and the standardization of relevant technologies are to be fulfilled. During the second period (1992-1996), the transmission network will be mostly digitized, the technology of ISDN will be domestically feasible, and the commercial service for ISDN will be available. The third period (1997 and after) will be characterized by an expansion stage during which the ISDN service will spread across the nation, and the various information and communication networks will be integrated into a single network, ISDN.

As a preliminary stage to fulfill this kind of plan, Korea plans to install a fiber-optical cable from 1992, divided into three stages shown as follows.[9]

During the first period (1992-1996), Korea Telecom plans to provide 1200 fiber optical transmission systems to 797,000 users, and formulate a demonstration city equipped with the fiber optical cable.

During the second period (1997-2000), about a thousand fiber optical transmission systems will be established around the area where high-rise apartments are congested in an effort to cover 4.65 million households. During the third period (2,006 and after), some 1,900 fiber optical systems will be additionally installed to cover 12.74 million households. By 2017, all user networks will be converted into fiber optics.

The plan for this ISDN will form an axial power along with a satellite plan to face up to the forthcoming information society in the 21st century. The developmental stage will comprise (1) the development and

experiment of ISDN, (2) the development of commercial technology for ISDN, (3) the establishment of demonstration service for ISDN, (4) the linkage of demonstration service to commercial service, (5) the development and establishment of the applied service model, (6) the plan and implementation stage for an ISDN to be internationally interactive.[10]

To fulfill this project for ISDN, First, Korea will need manpower enough to establish and operate ISDN. Second, the user service should be developed as well as expanded. Third, the necessity of ISDN should be expanded by increasing various new services.

Fourth, the technology of ISDN shall be standardized in order to maximize its service to industry.

Fifth, an international cooperation and competition will be encouraged to upgrade quality of this service.

V. Summary & Conclusion

As mentioned above, the field of telecommunications in Korea is supposed to advance its technology ultimately to fulfill an integrated ISDN service as this area of service is gradually open to competition.

The positive and consistent implementation for the KOREASAT project and ISDN plan will be vital to the national communication and information policy in that it is most likely to form the core in the coming information society. The integrated service-the ultimate objective in an information society, will be possible when the services of ISDN and satellite system are closely linked. This kind of linkage service is showed in the following diagram.

This kind of integrated service will not only improve the various communication and information services, but increase the potential of users. It is also most likely to upgrade the technology of telecommunications enough to compete internationally.

Regional Economic Integration or the Global Village

Donald McL. Lamberton
Centre for International Research on
Communication and Information Technologies
Melbourne, Australia

1. ABSTRACT

Are the developments in so-called intelligent electronics more conducive to regional economic integration than to progress towards the global village? How do they affect what Lee Kuan Yew referred to as "the intangibles", "the coherence of a society", and the ways in which societies link together?

THE GLOBAL VILLAGE: VISIONS AND REALITIES

For many the road to the global village has been mapped; it is smooth and well-defined. Having few doubts about the quality of life they believe the often startling developments in information and communication technologies enable us to achieve, they wish to hurry down this road to "the technological wonderland of tomorrow"(1). The machines, the terminology and the expectations are all in place. We have facsimile, ATMs, VCRs, CDs, cellular phones. Language now accommodates hypermedia, knowbots, and virtual reality. The wired city has been replaced by worldwide interconnectivity, replete with a myriad gadgets of intelligent electronics.

For The New York Times the 1980s were when information accelerated. The editorial marking the end of the decade declared that "The 1980s now bequeath to the 1990s their exhilaration and their acceleration - and, lest anyone forget, their relentless miseries. The poor. The addicted. The uneducated. As this decade was shaped by decades past, so it will shape the next"(2). Shifting our attention from the American to the world scene, we might note that the globalization process is not as far advanced and not as equitable in its impact as we have been led to believe. Over half the world's population is not yet within two hours walking distance of a telephone!(3)

Such aspects of reality are in sharp contrast to the buzzword usage. For example, in a recent Cadbury Schweppes advertisement in The Economist the word GLOBAL features prominently although there is nothing in the ad. that distinguishes any local, regional, international or global dimensions(4). It would seem that in this popular version of globalization, there is an implicit assumption that good and equitable use will be made of information. Technologies rather than information are apparently what matter. Information is thought of as like lubricating oil; its presence makes things work better - it assures wise decisions and efficient markets. It spreads further on a level surface, which, if it happens to be a playing field, incidentally helps ensure competition.

This simplistic view fails to reckon with a variety of costs: the costs of thinking, of agreeing, of foresight. It fails to reckon with a variety of constraints: psychological, cultural and organizational constraints. In Daniel Bell's words: The new production technologies emphasize small scales and regionalization, customization, and adaptability. But the structure of trade and exchange, of capital and currency, on the other hand, are becoming more worldwide and integrated. So what you have is a mismatch of scales. Actually, it is even more complicated than that. Production is becoming more local and regional; trade is becoming more continental; and capital and currency markets are becoming more international. So you're going to get continental economies of scale, regional economies for production, and international economies for capital and currencies. And where will the nation state be? It is caught in between all these conflicting elements (5).

Of course, we might wish to debate some elements of Bell's reasoning but he has set forth reasonable working hypotheses relating to the economic aspects.

These economic aspects are related to the constraints I mentioned. When we take account of those psychological, cultural and organizational constraints, steep gradients emerge as between those with phones and those without, those with information-handling capability or organizational capital and those without, those with information resources and those without. Invoke such conventional economic concepts as complementarity and investment and this information-intensive world displays significant asymmetries in, for example, income and innovation, and clearly

identifiable patterns of cohesion, such as, for example, regional trading blocs and the proliferating forms of international governmental and non-governmental institutional development(6).

ASYMMETRY AND TRADE

The trading possibilites that are fundamental to the functioning of an economy arise from individual differences. These asymmetries, especially those of information and organization, must be viewed in the context of the global economy. The word global means pertaining to or embracing the totality of a group of items, categories, or the like. In relation to economic activity, it would seem to imply, at a minimum, the involvement of all economies. But that involvement could well be limited, both in terms of the volume and variety of trade. At the other extreme - and this would seem to fit well with the popular global village thinking - there would be complete economic integration. Can there be anything that might be described as complete integration while individual differences of information and organization remain? Perhaps we should see the global economy with the set of individual economies showing diversity in respect of both position within this integration spectrum and overall size.

In one of the few theoretical papers that explore the workings of a global economy, Holland notes the following features:

1. The overall direction of the economy is determined by the interaction of many dispersed units acting in parallel. The action of any given unit depends upon the state and actions of a limited number of other units.

2. There are rarely any global controls on interactions-controls are provided by mechanisms of competition and coordination between units, mediated by standard operating procedures, assigned roles and shifting associations.

3. The economy has many levels of organization and interaction. Units at any given level typically serve as "building blocks" for constructing units at the next higher level. The overall organization is more than hierarchical, with all sorts of tangling interactions (associations, channels of communication) across levels.

4. The building blocks are recombined and revised continually as the system accumulates experience - the system adapts.

5. The arena in which the economy operates is typified by many niches that can be exploited by particular adaptations; there is no universal super-competitor that can fill all niches (any more than such would be the case in a complex ecology such as a tropical forest).

6. Niches are continually created by new technologies and the very act of filling a niche provides new niches (cf. parasitism, symbiosis, competitive exclusion, etc., in ecologies). Perpetual novelty results.

7. Because the niches are various, and new niches are continually created, the economy operates far from an optimum (or global attractor). Said in another way, improvements are always possible and, indeed, occur regularly(7).

Several features of such a model might be noted in this context. First, there is an important role for accumulated experience(8). Experience and learning are the basis of improved standard operating procedures that pemit more and more sophisticated interactions between units. If culture is "a living historical product of group problem solving"(9), it readily finds a place in this analytical framework. So too would a thoery of learning.

A second feature relates to limits on adaptability. Reliance upon accumulated experience can, because of the economic characteristics of information and the organizational arrangements for information-handling, lead to failure to satisfice, failure to search for better outcomes. Culture, as defined above, ceases to be part of social capital and becomes a burden. History matters and the process leads towards organizational obsolescence(10).

A third feature can be observed when an individual economy modifies the communication links it has with the rest of the global economy. Streeten analysed the interaction of communications and technology gaps in the development process(11). A communications gap means that the existing technology is only partly or imperfectly communicated. Technology gaps can be of two kinds: the first kind result from imperfections in communicating and transferring existing technologies; the second may be due to absence of appropriate technologies. This second kind he called the suitability gap. But the more and the better advanced technology is communicated, the less likely it is that a new and more appropriate indigenous technology will be developed. Better communication reduces both the opportunity and the will to invent an indigenous technology. Closing an economy off against foreign influences, and particularly against the multinational enterprise, may be the correct policy if we wish to close the suitability gap"(12).

This reasoning was applied to the development process. However, once we treat the individual economy, developed or developing, as an organizational economy, as an economy in which what happens in organizations may be even more important than what happens in markets(13), a more general meaning of appropriateness emerges.

Technology must be appropriate to the entire resource mix: labour, capital and organization. Is it not then possible also for domestically generated technology to be inappropriate? Perhaps this is currently the case with information technology. The American story is that information-processing equipment as a percentage of all the durable equipment bought by private enterprise (excluding farms) increased from 11 per cent in 1970 to 51 per cent in 1989. In the words of The Economist, corporate America "gorged itself on information technology"(14). "Employees and information technology are companies' two biggest single expenditures. But the marriage of the two has proved most unproductive "(15).

Assigning an organizational, information-using character to the economy and its operational units may have brought greater complexity to our analysis but that may have been a price worth paying. An information-theoretic viewpoint allows a role for learning, the design of organization, sequential behaviour, time lags, and consequential diversity.

AN INFORMATION-THEORETIC VIEW OF OPTIMAL TELECOMMUNICATIONS INVESTMENT

Mainstream economics does not have a perspective on technology and the future of the information and communication industries. In so far as it has failed to recognize limitations upon our capabilities to gather and process information, to communicate, decide, and to agree amongst ourselves, mainstream economics has in effect denied the possibility of any special role for these industries. What is needed is an information-theoretic view that reckons with information processing as the dominant resource -using activity(16); a continuous activity(17) in which information is a form of capital; information is costly; information-dependence can lead to organizational obsolescence; and we have much to learn about the design of organizations(18).

If information - and it must be emphasized that technology is perhaps the most important kind of informtion - is a capital resource, we should look not only at the substitution effects that reflect powerful forces leading to the adoption of technology, but also to the way in which the various kinds of information complement each other. Because information flows are the essence of economic dynamics, the notion of complementarity here must be extended and must embrace co-evolving technologies with applications spreading into many industries. External effects in the accumulation of knowledge have a critical role in economic development(19). ICTs and the new materials technologies are an excellent illustration of this co-evolving, complementary character.

The extent of the spillovers and the interactions reflect the communication infrastructure. We must, however, be very careful in interpreting the word, infrastructure. The most common error, and one that can have quite disastrous consequences, is to equate technology in the hardware sense, i.e., equipment, with information and even with the use of information. This is done because it seems to permit the adoption of the tangible ICT equipment to be presented as a measure of how well the economy is handling the intangible information(20). In many economies where there is heavy expenditure on ICT, the reality may well be "Spending more; knowing less". Better design of organizations, more interpersonal communication and more evaluationmight well make a better contribution to economic growth. In fact, one researcher argues that US manufacturers would have done better, between 1978 and 1984 had they directed the capital invested in information technology to almost any other part of their businesses(21).

The ideas developed in the earlier sections of this paper can be applied to investment in telecommunications.

Good telecommunications are at the same time a cause, a consequence and a manifestation of development: they are one of the many contributing factors to economic growth and industrial expansion, rich countries can afford to spend comparatively much more on telecommunications services than poor countries, and available data show a close positive correlation between a country's wealth per head and the density of its telecommunications system(22).

A less balanced view emphasizing the casual role and concluding that there is substantial under-investment is widespread. It should be met with caution. We have seen other simplistic interpretations of the development process that lead to 'solutions' in terms of power generation, capital investment or the provision of technical skills. Economists should, given their inclination to stress the interdependence of the component parts of an economic system, be suspicious of such single-factor explanations, and yet they may fail to get to the core of the problem - the role of organization in the economy. All too often, they place this in the non-economic category and fail to understand that even a 'balanced' investment program can be ineffective because organizational structures are either obsolete or inappropriate. In the case of telecommunications technology, it seems necessary to remind many that the demand for telecommunications services is a derived demand- a demand that derives from the value of information used or computations made. That value in turn depends upon the 'states of readiness' of those individuals or organizations receiving it. Appreciation of this dependence requires consideration of organizational aspects.

The debate about the evaluation of telecommunications investment has been too narrowly confined. True, some features at the national level have been highlighted. The need for developing countries to use scarce foreign exchange reserves is usually mentioned. So, too, is the structure of the world telecommunications equipment supply industry and the price differentials that might result from industry strategies. But in both cases there is need to look to the general economic context. Foreign exchange may have to be rationed for all purchases of foreign technology, goods and services; and monopoly elements may pervade all the markets in which developing countries operate. It is not, therefore, practicable to treat the telecommunications system in isolation from the rest of the economy and its operation, including changes in the level of investment in the telecommunications system itself, must be judged in terms of effects on the entire economy - an analysis that begins with the derived demand relationship.

What allocation of telecommunications investment as per cent of GDP is optimal? To answer this we must ask further questions. What complementary investments are needed? What effects could be attributed to the changed telecommunications situation? How is the investment calculated: does it include the engineering and human capital? Does it include organizational capital? How important are monopoly elements in the pricing of equipment and technology acquired from abroad? Such considerations call for a wide-ranging cost-benefit study and comparison with alternative investment programs in, for example, health, education, transport, etc.

It is now clear enough that all countries will have to become users of new telecommunications technology but it seems likely that only some will, by so doing, gain the comparative advantage they are seeking. The importance of economic research in seeking out those advantages is to be found in some basic perspectives it can bring to major policy matters rather than in the equations of its too mathematical journals. In terms of the optimal telecommunications investment problems, economic analysis must emphasize both the complex interdependence between the use of telecommunications and the whole range of economic activities and the process nature of economic development. Cost-benefit calculations of the 'snap shot' kind inevitably miss a great deal of both costs and benefits and can be thoroughly misleading. Whatever the methods adopted to win a larger share of national resources, those responsible for telecommunications planning must be aware of the preconditions, the sequences and the lags that are involved in the technical choices within the telecommunications system.

Those planners mostly fail to come to grips with the preconditions, sequences and lags that arise from the telecommunications system being part of both a domestic and international economy. Those relationships are extremely complex but optimal decisions or even just reasonably sound decisions require some understanding of them. In the development context, "information is poor, scarce, maldistributed, inefficiently communicated and intensely valued"(23). Telecommunications systems cannot solve all these problems but they do have an important contribution to make - a contribution that is much enhanced by achieving a better designed infrastructure in all its dimensions.

Design of that infrastructure depends a great deal on certain characteristics of telecommunications. The most emphasized of those characteristics is probably its friction-reducing capability(24), the importance of which reflects the extent to which (a) telecommunications does in fact provide a uniform distribution of information over space; and (b) the technology and its applications are adopted by a significant share of growing information-dependent markets. In relation to regional patterns, the following need to be taken into account:

* the scale effect;
* the prior geographical distribution effect;
* information demand;
* organizational structure; and
* logistics(25).

A combination of these circumstances can moderate the initial perceptions of benefit. While the new technologies make it possible for agents to reach out from their home base and to more easily draw information from their environment, the same is true for others outside. And once made dependent upon the new facilities, agents may find that they are subject to new forms of control. Symbiotic relationships that develop gradually may hold the best prospects of benefit and may well serve as the basis for new groupings and regional blocs (26).

We should not be surprised then at the finding that "Telecommunications is reinforcing the commanding role of major business concentrations around the world ... New information technologies do have a fundamental impact on societies, and therefore on cities and regions, but their effects vary according to their interaction with the economic, social, political, and cultural processes that shape the production and use of the new technological medium (27).

Some of the integration and globalization trends seem likely to be reversed. Global dreams have already proved to be tunnel vision for financial and advertising interests. As The Economist remarked: "financial markets may indeed have turned global, but that does not mean that every financial intermediary must build a costly worldwide network. The business and the variables that determine competitive advantage are more complicated than that"(28).

Psychological distance and the limits of organization seem likely to ensure that a medieval Mediterranian trade route model will have more relevance to the near future than will the technological wonderland model of the global village. Even if Marshall McLuhan's ideas are to prove correct, the time dimension may be very long term indeed. The nearer future, I suspect, will grow out of the interaction of localized and McLuhan forces; an interaction that leaves a good deal of room for action that evolves from past experience and uses the existing resource and knowledge base. So we shall travel slowly, learning as we go, in a world of local, regional, continental and international dimensions.

The Canada - US FTA: Telecom and Regional Free Trade

Hudson Janisch
Faculty of Law
University of Toronto

1. Introduction

In this panel we will be seeking to address the overall question as to whether IT developments are more conducive to global (in the context of the PTC, Pan Pacific) or regional blocs. The purpose of this paper is to draw attention to the specific terms of the Canada-U.S. Free Trade Agreement (FTA) and to suggest that the FTA exemplifies the role telecommunications will play in regional economic integration. From my vantage point as a Canadian legal academic with an abiding interest in telecommunications policy and regulation, it would seem that the initiative lies with telecom furthering regional blocs rather than truly international Pan Pacific developments. Whether a North American regional trading bloc becomes a protectionist fortress or acts as a springboard for further free trade, and what role international telecom will play in all this, is, of course, The Big Question. My paper will focus on more parochial and specific concerns. However,I would argue that any attempt to address the wider issue will founder if we do not have some very precise information as to what is actually going on out there. We need to be muddled with a few facts!

2. The Historical Bilateral Transborder Regime

The development of Canada-U.S. telecommunications has been influenced by a number of factors. Historically, the exchange of telecommunications traffic across the U.S.-Canada border was greatly facilitated by the institutional similarities in the provision of telephone service. While Canada never developed a single separate long distance carrier such as AT&T Long Lines, the existence of provincially-based monopolies made it relatively simple to arrange for the exchange of traffic on a company-to-company basis. Over time, a wide range of agreements was established between Canadian carriers and AT&T which allowed for revenue settlements very similar to those already established domestically. As well, Canada adopted similar technical standards to those of the U.S., is part of the North American Numbering Plan, and the two countries have fully integrated telecommunications network infrastructures. Indeed, perhaps nowhere in the world are there two more integrated national systems. The Canada-U.S. trans-border regime has until recently been premised on the same principles as those governing the multilateral regime. There have been some striking differences, however. Perhaps the most important is the fact that, unlike the multilateral regime which given that it is treaty-based is naturally governmental in nature, the Canada-US regime has been essentially non-governmental. Although the FTA alters this somewhat, apart from several recent transborder satellite and data agreements, private not public ordering of relationships based on negotiated reciprocal advantages of exchanging traffic, has predominated.

The second major feature of the trans-border regime is that it has always been deliberately excluded from the larger international regime. Thus in 1988, the United States adopted the following position in the Final Protocol on International Telecommunications Regulations: "The United States of American formally declares that it does not, by signature of these Telecommunications Regulations, nor by any subsequent approval thereof:... c) accept any obligation in respect of the application of any provision of these Regulations to service within the United States on the one hand, and Canada, Mexico, and Saint-Pierre and Miquelon Islands on the other hand, and to the rates applicable to such service.".

3. The FTA Introduced

There has been a tendency to underestimate the importance of the FTA's provisions governing telecommunications. It is true that only computer and enhanced services are covered (with

definitions of what is included apparently left to national regulators), much existing law and policy is grandfathered, and provision is made only for national treatment, not full market access. Just the same, this recitation of limitations should not lead to the conclusion that the Agreement is in any way insignificant. In the first place, computer and enhanced services constitute a crucially important growth element in modern telecommunications. Enhanced services in Canada currently include Data Access Arrangements (a packet-switched data service), Radio Paging, Envoy 100 (a text message service), INET 2000 (a messaging and data based service), TELENET, TELTEX and TELPOST, Store and Forward Telex, Telegraph, and 911 Service. As this list of services shows, there are still relatively few enhanced services in Canada today, and they represent only a very small part of the telecommunications market. Nevertheless, there is every reason to believe that enhanced services will become increasingly more important in future. For example, there are today fewer two-way real time voice conversations with the advent of store-and-forward voice mail and electronic mail services. Other enhanced services such as home shopping and banking , and data base access and retrieval will soon grow in significance. Second, closer analysis reveals that important restraints have been placed on national regulators with respect to the crucial issue of definitions. Third, it does not appear that older policies have been automatically grandfathered with respect to measures required to prevent anti-competitive practices in the provision of enhanced services. Fourth, and most important, limited as the provisions of the Agreement may be, they mark the very first occasion that an international agreement has dealt with trade in telecommunication services. Indeed, telecommunication services is one of only three service sectors dealt with by way of a separate sectoral annex - Annex 1404C, "Computer Services and Telecommunications-Network-Based Enhanced Services." While the FTA represents more a cautious affirmation of the status quo between countries with relatively liberalized domestic arrangements than any clear signpost towards future multi-lateral agreements, the pioneering nature of the achievements of the negotiators of the Agreement need to be recognized. Indeed, given Canada's intransigent refusal to allow competition in long-distance public voice service, a corner-stone of U.S. policy, it is remarkable that anything was achieved at all in the telecommunication services sphere.

4. Why Only Computer and Enhanced Services?

Negotiations leading up to the FTA took place against a backdrop of a sharp difference in policy between Canada and the United States with respect to the role that competition should play in telecommunications. Just how highly charged this difference was may be seen in a contemporary speech of the federal Minister of Communications in which he was moved to express his condolences to the American people for the pointless destruction of a superb integrated network with the divestiture of AT&T and to promise that Canadians would never suffer a similar fate. Whatever happened, they were to be protected from "déréglementation brutale."

Yet wide as was the gap on long-distance voice competition, the incompatibility of the respective national approaches toward competition was not total. Competition had been allowed in Canada in private voice and data services, in resale and sharing, in cellular services and in terminal equipment, as well as with respect to enhanced services. It was thus possible for the negotiators to segment out computer and enhanced services for inclusion in the Agreement. Before turning to look at how this was done, it might be useful to deal briefly with the telecommunications equipment issue.

5. Integrating the Equipment Markets

In 1986, Canadian exports of telecommunications equipment to the United States amounted to $781 million, while Canadian imports amounted to $694 million. This was up from $487 and $280 million, respectively, in 1982. In 1986, the United States accounted for approximately 62 per cent of Canadian exports, and 57 per cent of Canadian imports. Canada, in turn, accounted for around 11 per cent of U.S. exports, and 13 per cent of U.S. imports of telecommunications equipment. Until 1 January 1989, tariffs on telecommunications varied widely -

Canadian duties on U.S. products ranged from 6 to 17 per cent, and resulted in a 3 to 7 per cent price disadvantage for U.S. producers. The tariffs for telephones, key systems, and private branch exchanges (PBX) were removed immediately upon implementation of the FTA in January 1989. Large switching systems were to have duties removed in three equal steps, leading to duty free status on 1 January 1991. All remaining transmissions equipment will be duty free by 1 January 1993. Fibre optic and coaxial cables have the longest tariff reduction schedule and will only become duty free by 1 January 1998.

It is interesting to note that tariffs on telecommunications equipment were originally scheduled to be phased out gradually over five years. But Canada's chief negotiator, Simon Reisman, has stated that at the urging of AT&T and other U.S. telecommunications equipment companies, Canada agreed to speed up tariff removal on some major products.

Given this background, it is not surprising to find Ken Lindhorst of AT&T expressing some satisfaction with the tariff aspects of the Agreement at the American Bar Association Convention, held in Toronto in 1988. The tariff treatment of telecommunications hardware was considered to be "the most positive element to be introduced in the Agreement." By contrast, procurement was characterized as the "most negative."

In recent years, Northern Telecom has occupied a remarkably advantageous position as a consequence of having, with Bell Canada, a common parent in Bell Canada Enterprises (BCE). As a preferred supplier, Northern Telecom has been given the opportunity to provide new telecommunication systems and equipment before requests are forwarded to other suppliers. With an assured domestic market resulting from this preferred access, Northern Telecom has been very successful in penetrating the U.S. market just at the time that the divestiture of AT&T greatly reduced any incentive for the Bell Operating Companies to stick with AT&T equipment. In the vernacular, Northern Telecom had it coming and going, "monopoly at home and competition abroad." Or to put it somewhat less crudely, "preferred access at home, equal access abroad."

This advantageous state of affairs is reflected in Canada-U.S. trade in telecommunications equipment. About two-thirds of Canada's $2.5 billion equipment market is supplied by Northern Telecom, with Bell Canada purchasing 85 per cent of its equipment from its preferred supplier. Northern Telecom has also enjoyed enormous success in the U.S. market, which now provides about two-thirds of its overall revenues.

Not unexpectedly, this contentious issue of preferential procurement has been the subject of bilateral consultations over the last four years between U.S. and Canada. Despite these concerns, this matter was not dealt with in the FTA, an issue of continuing concern to AT&T.

U.S. telecommunications equipment manufacturers have not been content simply to await developments; they made their move under the Omnibus Trade and Competitiveness Act of 1988 in an effort to gain thereby what they had failed to obtain in negotiations leading up to the FTA. Part 4, "Telecommunications Trade," of that Act provides the "crowbar" that the Americans proposed to use to achieve "an open world for trade in telecommunications products, services and investment." Section 1394(a) of the Act requires the United States Trade Representative (USTR) to "conduct an investigation to identify priority foreign countries" for the purposes of the telecommunications provisions of the Act. In its first report, the USTR has designated the European Community and Korea as "priority foreign countries."

While it is far from clear exactly what steps were taken by U.S. equipment manufacturers, it was reported that they had sought to have Canada designated as a priority country, and that the USTR decided not to do so in view of the adverse impact this would have on the implementation of the but recently concluded FTA and in view of the relatively weak case that could be made against Canada. While not raised directly by the FTA, a much larger issue is looming on the horizon. Given the huge development costs of digital switches (and the optical switches yet to come) and nearly saturated markets (dreams of China and the Soviet Union notwithstanding), it

is expected that there will be further consolidation in the near future in switch manufacturing. While Northern Telecom is seen as likely to survive, it may only do so by entering into an alliance with another large-scale manufacturer seeking access to North American and European markets, such as Ericsson. This would immediately raise highly sensitive issues, as Northern Telecom is widely perceived as Canada's one and only information technology superstar. Already there is deep concern that technology development (let alone manufacturing capacity) is being moved south. While well beyond the scope of this paper, it is evident that Canadian policy-makers need to start thinking through the implications of globalization for large-scale telecommunications equipment manufacturing in general, and for Northern Telecom in particular.

6. A Question of Standards

Given the nature of the telecommunications industry, there is always the danger that standards will be used as non-tariff barriers to trade. (The most notorious recent example of this has been in Japan-U.S. trade relations, although there has been much improvement in this regard in recent years.) Both Canadian and U.S. exporters of telecommunication products benefit from the fact that their national systems operate on compatible standards. However, each country's products still must meet certain national standards in the other country. In the past, U.S. companies have claimed that Canadian requirements are unreasonably more cumbersome than those in the United States, and that this places them at a disadvantage by slowing down the entry of their products into our markets. To support their charges, the Americans point to the Federal Communications Commission's (FCC) requirement that imported equipment must not lead to "harm to the network," while Canadian regulation requires that positive "performance" standards must be met. It was reported that U.S. negotiators at the free trade talks proposed that Canadian testing procedures be liberalized. In the end, while a general prohibition against the use of technical standards as disguised barriers to trade was included in the FTA, nothing was included specifically with respect to telecommunications equipment. The issue does not appear, however, to be a serious one, with residual concerns confined to relatively minor matters of expense and time.

However, in one area, the general commitment to eliminate the use of standards as a barrier to trade could emerge as important. The implementation of the integrated services digital network (ISDN) will most probably stimulate increased demand for a wide range of new terminal and subscriber equipment. Domestic producers on both sides of the border may be tempted to resurrect "network compatibility" arguments in order to exclude foreign suppliers from competing in emerging markets for ISDN equipment. While the FTA does not prevent either country from establishing national standards, it does require that foreign suppliers be granted equivalent access to domestic suppliers if it can be demonstrated that their products meet objective standards imposed by the authorities in either country.

7. The Telecom Sectoral Annex

Article 6 makes the limits of the Sectoral Annex very clear. As a result of an abundance of caution, specific exceptions are spelled out therein. They provide, first, that there is neither a right nor an obligation on the part of either Canada or the United States to authorize the operation of basic telecommunications transport facilities or services by "persons" of the other country. Second, nothing in the FTA precludes either country from maintaining, authorizing or designating monopolies for the provision of basic telecommunications transport facilities or service. Third, each country is permitted to mandate the use of its own basic telecommunications network for internal traffic as well as any traffic originating or terminating in that country. Canadian authorities have already announced that a statutory obligation will be placed on its carriers to employ Canadian facilities whenever feasible.

Cumulatively, the exceptions outlined in Article 6 go a long way to retain sovereignty over "basic" telecommunications. But what of "enhanced" services?

(a) **The Definition Issue**

It will come as no surprise to you to learn that certainty in language and operation were not achieved in the FTA! Yet, because inclusion is limited, definitions will be all important.

Definition-making and construing have been a very difficult process in contemporary telecommunications regulation due to the ever changing nature of technology and the myriad new services it makes possible. One only has to recall the FCC's desperate efforts to distinguish between "telephones" and "computers" and, later, "enhanced" and "basic" services, or Judge Greene's decisions on the line-of-business limitations for the Bell Operating Companies, to realize that, whatever definitions are included in the FTA itself, what is going to be crucial is who decides what is or is not a "basic" as opposed to an "enhanced" service, or what is or is not included as "computer services."

"Basic" telecommunications are said in the Agreement to mean any service, as defined and classified by measures of the regulator having jurisdiction, that is limited to the offering of transmission capacity for the movement of information. "Enhanced" service is said to mean any service offered over the basic network that is more than a basic telecommunications service, as defined and classified by measures of the regulator having jurisdiction.

An initial reaction might be to believe that basic and enhanced are whatever they are defined to be by the respective national regulators. Does this then mean that a Canadian regulatory agency could define as "basic" what its U.S. counterpart would undoubtedly consider as "enhanced" - thereby protecting its monopoly telephone company from competition? It would not appear so. This is because "basic" is declared in the Agreement itself to be limited to the offering of transmission capacity for the movement of information. Should the service, looked at objectively, be more than simple transmission, then the regulator would be without authority to deem it "basic."

"Computer services" are somewhat more straightforwardly and comprehensively defined as services - whether or not conveyed on the basic telecommunications network - that involve generating, acquiring, storing, transforming, processing, retrieving, utilizing or making available information in a computerized form, including, but not limited to: computer programming; prepackaged software; computer integrated systems design; computer processing and data preparation; information retrieval services; computer facilities management; computer leasing and rental; computer maintenance and repair; and other computer-related services, including those integral to the provision of other covered services.

This makes it apparent that the FTA contemplates the direct provision of computer services outside of a telecommunications context. With this in mind, it must be read in the wider context of services as a whole, and particularly, the Sectoral Annex on Temporary Entry for Business Persons, which will greatly ease transborder movement of computer service, sales, management, installation and maintenance personnel.

(b) **Effective Measures to Prevent Anti-competitive Conduct**

Under article 5 of the Sectoral Annex the obligation is to ensure that the monopoly shall not engage in anti-competitive conduct in the enhanced services market, and to maintain, or introduce, effective measures to prevent anti-competitive conduct. Moreover, this obligation is to be construed in accordance with a sectoral objective of supporting the further development of an open and competitive market for the provision of enhanced and computer services. The issue that then arises is whether current Canadian regulatory practices measure up to this new international obligation.

(i) **Accounting Requirements**

Over the last twenty years, major strides have been made by the federal regulator with respect to costing. Indeed, Canada has displayed great aversion to structural changes such as divestiture (and even separate subsidiaries) and has put its faith in conduct regulation and cost allocation. Initial contribution tests have given way to Phase II of the mammoth Cost Inquiry which involves the preparation of an economic evaluation of new services using an incremental approach to show that it will have a positive net present value over its useful life. Phase III provides for a

costing methodology which divides costs and revenues into a number of categories. Finally, when Bell Canada applied to introduce ALEX, a network based gateway service which allows customers with a videotext terminal or personal computer to access electronic information or transaction services, the CRTC developed a unique method for detecting cross-subsidization. It required Bell to identify and forecast all the costs and revenues associated with the market trial and to report on a quarterly basis. The regulators have, in effect, developed, a whole new accounting methodology to ensure that costs are not subsidized by any other services in either the monopoly or competitive network services category.

The crucial question for us in this dance macabre of costing methodologies is whether any of these accounting requirements meet the FTA's standards. Careful analysis will allow us to determine whether a regional agreement really has the potential to change one country's domestic regulatory regime in a manner which will allow for further integration via enhanced services. Such services, in turn, will, no doubt, facilitate yet broader economic integration.

The contribution test can in no sense be regarded as effective. As for the Phase II methodology, its fatal flaw is that actual revenues and actual costs may well be very different from even the best projections. Since the Phase II methodology does not include a method of reviewing on an annual basis whether cross-subsidization is actually taking place, it would appear that this form of accounting requirement would not satisfy Article 5.

Phase III results probably would not, in and of themselves, satisfy Article 5. As with the contribution test, it is possible for enhanced services to be subsidized by other "competitive" services. Only the methodology imposed for the ALEX market trial would appear to satisfy fully the requirements of the FTA. The methodology is scrupulous to ensure that enhanced services are not cross-subsidized. In addition, it has a benefit over the aggregate enhanced services study in that each individual service can be shown not to be subsidized. With an aggregate enhanced services study, some enhanced services may subsidize other enhanced services. This may be considered to be cross-subsidization or predatory conduct, both of which are prohibited forms of anti-competitive conduct under Article 5. The ALEX trial rules eliminate these problems. It may be no coincidence that the ALEX trial methodology was developed by the CRTC after the FTA was concluded and passed into law.

(ii) Structural Separation

The most direct way to avoid the cross-subsidization problem is to require the carrier to provide the competitive service through a structurally separate subsidiary. In this way, the assets used to provide the competitive service are not included in the rate base and cross-subsidization cannot occur. The structurally separate subsidiary can be required to obtain services from the regulated carrier at the same rates as all competitors. Since each corporation is a separate corporate entity with its own books, the relationship between the competitive and monopoly services could be scrutinized. The FCC, in its Computer II decision, required structural separation for carriers wishing to provide enhanced services. In its Computer III decision, however, the FCC began to move away from structural separation and indicated that when open network architecture (ONA) has been approved, structural separation will no longer be required.

Although structural separation is an excellent mechanism for preventing cross-subsidization and other anti-competitive practices, it has substantial drawbacks. For instance, customers who want to acquire both competitive and monopoly services from one supplier are denied the benefits of one-stop shopping. In addition, the carriers cannot take advantage of economies of network scale and scope which may be present if both the monopoly and competitive services are provided by a single corporate entity.

In Canada, there has been but little experience with structural separation in the enhanced services market. There is, however, some limited experience in the radio-telephone market.

Both Bell Canada and B.C. Tel have been required to set up arm's length affiliates to provide cellular telephone services. It is

widely agreed that the use of structural separation in the cellular market has worked well. But, in March 1986, the CRTC announced that it would not require Bell or B.C. Tel to provide competitive multi-line and data terminal equipment through a separate affiliate.

In assessing whether a separate subsidiary could ever be required under the FTA, it should be most carefully noted that the move away from separate subsidiaries in the U.S. came about only when it was determined that open network architecture could prove to be an adequate substitute. This approach is captured in the reference in Article 5 to "disclosure."

(iii) Disclosure

Where the carriers provide enhanced services, they will know more than their competitors about plans for the evolution of the basic network. Accordingly, it may be less expensive for the carriers to provide enhanced services, and they may be able to introduce these services to the marketplace more rapidly than their competitors. It is therefore important for the carriers to provide information about network plans to enhanced service providers.

In Telecom Decision CRTC 84-18, the CRTC dealt with this issue. It concluded that competitors would receive sufficient network planning information through participation in construction program reviews and general rate proceedings. Given that Article 5 specifies "disclosure" as one of the remedies for anti-competitive conduct, it is doubtful whether the level of disclosure mandated by the CRTC is sufficient. Significantly, the "Report on ISDN Implementation in Canada", issued in March 1989, has called for disclosure of carrier plans on a timely basis.

(iv) Grandparenting

Generally the FTA is prospective. But, a careful reading of paragraph 5 of Article 1402, along with Articles 1403 and 1404, seems to indicate that, while rules and regulations relating to national treatment, and licensing and certification are grandfathered, rules and regulations relating to a different matter, cross-subsidization in the enhanced services market, are not. The better view would seem to be that the grandfathering provisions of Article 1402 do not apply to Article 5 of Sectoral Annex 1404 C. In this view, Article 5 of the Sectoral Annex is indeed meant to affect existing regulations. This would appear to be more in keeping with its requirement to introduce effective measures to guard against anti-competitive conduct.

(v) Collaboration between Regulatory and Competition Authorities

As well as concern for cross-subsidization, Article 5 speaks to predatory conduct and the discriminatory provision of access to basic facilities or services. Canada has thus far not had a happy experience co-ordinating regulatory and competition policies. What thinking there has been on this issue has been stunted by an extravagant version of the regulated conduct exemption. It is far from clear how the FTA can and will be used to augment existing provisions of the competition law dealing with price discrimination, predatory pricing, and the like.

(vi) Commercial Presence and Investment

Paragraph 2 of Article 3 of the Sectoral Annex provides for the establishment of a commercial presence which includes, "the establishment of offices, appointment of agents, and installation of customer-premises equipment or terminal equipment for the purpose of distributing, marketing, delivering or facilitating the provision of an enhanced or computer service." This does not appear to address what is emerging as a serious limitation on the further development of the enhanced services market. Current Canadian regulatory policy effectively prohibits the ownership and operation of any transmission facilities by non-basic carriers. There is room to doubt whether enhanced service providers could function effectively if they are not allowed to own and operate at least some of the transmission facilities utilized.

Given that the objective of the Sectoral Annex is to support the further development of an open and competitive market, there is room to argue that paragraph 3's statement that investment shall include the purchase of "equipment necessary for the provision of enhanced or computer services" should be stretched to cover a limited range of transmission facilities as well.

8. Lessons from the FTA
